# Acknowledgements

The Health Research Council of New Zealand initially funded the NZCMS. The Ministry of Health now funds the NZCMS.

Many staff of SNZ have contributed to both the development of the NZCMS. In-particular for the 2001-04 update we would like to thank John Upfold, Ann Jebson, Tim Blackburn who are all involved with the SNZ Datalab; Ricardo Namay and Anapapa Mulitalo for the record linkage; Steve White for the final census datasets; and Pauline Stuart and GuanYu (Fish) Zheng for confidentiality checking.

From NZHIS we wish to acknowledge the help of Chris Lewis.

Numerous people from the Ministry of Health have also provided strong support. Martin Tobias has provided advice and guidance throughout.

Finally, there is a larger team of researchers and co-investigators involved with the development of the NZCMS 2001 cohort than those who authored this report.

# Executive Summary

## Linkage of 2001-04 mortality records to 2001 census

- Overall, 81.5% of eligible mortality records (all ages) in the three years after the 2001 census were linked back to a 2001 census record (67,146 linked pairs).
- We estimated that over 97% of these linked pairs were correct linkages.
- Mortality records were less likely to be linked to a census record if: age 25-34 years; external cause of death; north of North Island; Pacific and Asian (and to lesser extent Māori) ethnicity compared to European/Other. Accordingly, we calculated linkage weights to 'weight up' the linked pairs to be representative of all eligible mortality records.
- Importantly, linkage success did not notably decrease with increasing time after census – probably a function of greater geocode information available than with previous NZCMS linkages.

## Numerator-Denominator bias: comparing ethnic counts on mortality data with that on census data

- Previously, we have found that Māori and Pacific deaths are grossly undercounted (and European/Other overcounted) on mortality data relative to census data, till the mid-1990s at least.
- We created a limited data set of highly probable census-mortality links, and used weighted analyses of these to compared ethnicity recorded on mortality and census files.
- There were negligible differences between mortality and census data in the number of Māori, Pacific, Asian and European/Other people enumerated using *total ethnicity* concept. This is good news for the health sector, demonstrating that the change in the ethnicity question on the death registration form, and other activities to encourage accurate ethnicity recording by undertakers, has been largely successful. However, it should be noted that much fewer mortality records had two or more self-identified ethnic groups compared to the linked census data.

# Recommendations

The lack of fall off in the linkage success of mortality records with increasing time since census night suggests that linking all five years of mortality data post census night to the prior census is feasible. This would have several advantages:

- Increased numbers for analyses
- Full coverage over time for improved monitoring (e.g. data points could be constructed by 2.5 year intervals, or even yearly intervals)
- Increased timeliness of monitoring information (e.g. rates for the 2004-06 period could be ready in 2010, rather than waiting to 2012 for 2006-09 rates)
- A simpler study design.

The key disadvantages to linking five years of mortality data back to census data are an increased effort, and some marginal increase in cost (although this would be small if each census was only linked once to the complete five years of mortality data).

We recommend that the Ministry of Health and the NZCMS lead investigators opt for one of the options below:

1. Link 2004-06 mortality to 2001 census as soon as possible and report findings. Then undertake linkage of mortality data to census data and reporting of trends in inequalities every 2.5 years thereafter. (This option involves two linkage projects for each census.)
2. Link 2004-06 mortality to 2001 census as soon as possible and report findings. Then undertake linkage of mortality data to census data and reporting of trends in inequalities every 5 years thereafter. (This option involves only one linkage projects for each census, but also means results for each census-cohort will not be available until 8 or so years after the baseline census date).
3. Proceed as per previously (i.e. just link 3 years of mortality data back to each census.)

# Statistics New Zealand Security Statement

The New Zealand Census-Mortality Study was initiated by Professor Tony Blakely and his co-researchers from the Wellington School of Medicine, University of Otago. It was approved by the Government Statistician as a Data Laboratory project under the Microdata Access Protocols.

## Requirements of the Statistics Act

Under the Statistics Act 1975 the Government Statistician has legal authority to collect and hold information about people, households and businesses, as well as the responsibility of protecting individual information and limits to the use to which such information can be put. The obligations of the Statistics Act 1975 on data collected under the Act are summarised below.

1. Information collected under the Statistics Act 1975 can be used only for statistical purposes.
2. No information contained in any individual schedule is to be separately published or disclosed to any person who is not an employee of Statistics New Zealand, except as permitted by sections 21(3B), 37A, 37B and 37C of the Act.
3. This project was carried out under section 21(3B). Under Section 21(3B) the Government Statistician requires an independent contractor under contract to Statistics New Zealand, and any employee of the contractor, to make a statutory declaration of secrecy similar to that required of Statistics New Zealand employees where they will have access to information collected under the Act. For the purposes of implementing the confidentiality provisions of the Act, such contractors are deemed to be employees of Statistics New Zealand.
4. Statistical information published by Statistics New Zealand, and its contracted researchers, shall be arranged in such a manner as to prevent any individual information from being identifiable by any person (other than the person who supplied the information), unless the person owning the information has consented to the publication in such manner, or the publication of information in that manner could not reasonably have been foreseen.
5. The Government Statistician is to make office rules to prevent the unauthorised disclosure of individual information in published statistics.
6. Information provided under the Act is privileged. Except for a prosecution under the Act, no information that is provided under the Act can be disclosed or used in any proceedings. Furthermore no person who has completed a statutory declaration of secrecy under section 21 can be compelled in any proceedings to give oral testimony regarding individual

information or produce a document with respect to any information obtained in the course of administering the Act, except as provided for in the Act.

### **Census data**

The Population Census is the most important stocktake of the population that is carried out. The statistics that are produced provide a regular picture of society. Results are used widely in making decisions affecting every neighbourhood. They are used in planning essential local services, and they also help to monitor social programmes ranging from housing to health.

Traditionally census data is published by Statistics New Zealand in aggregated tables and graphs for use throughout schools, business and homes. Recently Statistics New Zealand has sought to increase the benefits that can be obtained from its data by providing access to approved researchers to carry out research projects. Microdata access is provided, at the discretion of the Government Statistician, to allow authoritative statistical research of benefit to the public of New Zealand.

This project used anonymous census data and mortality data which were integrated using a probabilistic linking methodology to create a single dataset that allows the researchers to undertake a statistical study of the association of mortality and socio-economic factors. The project has been closely monitored to ensure it complies with Statistics New Zealand's strict confidentiality requirements.

### **Further information**

# Glossary

<b>Area unit (AU)</b>	An administrative unit referring to a geographically defined population group of around 2,000 individuals. Area units are used by Statistics New Zealand, particularly in relation to census data (thus the term Census Area Unit or CAU).
<b>Array</b>	Where more than one value is presented for the same variable (e.g. some mortality records contain two different dates of birth for the same individual – one from the NHI database and the other from the NMDS database).
<b>AutoMatch®</b>	The original version of the software package for carrying out probabilistic record linkage. The latest version is called QualityStage™
<b>Bias analysis</b>	Estimating any systematic differences between linked and unlinked mortality records (i.e. analysis of linkage bias).
<b>Blocking variable</b>	A variable used to break down large files into smaller subsets, to limit the number of possible comparison pairs. Comparison pairs are only formed when the blocking variable agrees exactly.
<b>Blocks</b>	The subsets resulting from blocking of larger files.
<b>Clerical review</b>	Investigator review of the records in a comparison pair, in order to decide whether or not these records are likely to apply to the same person. Clerical review usually occurs only for comparison pairs with a total weight within the cut-off range for the relevant linkage pass.
<b>Cohort analysis</b>	Epidemiological analysis of linked census-mortality cohort datasets to determine differences in mortality rates by social factors. (This is the primary aim of the New Zealand Census-Mortality Study.)
<b>Comparison pair</b>	Any possible comparison of a record from one file with a record from another file. In the NZCMS, comparison pairs consist of one census and one mortality record.

<b>Cut-off weight</b>	The total weight used as a threshold to decide which comparison pairs to accept as links, and which to reject. This weight is usually expressed as a discrete value, but may also be expressed as a range (where upper value = <i>acceptance weight</i> , lower value = <i>rejection weight</i> ); in this case, all comparison pairs falling within the cut-off range are subjected to clerical review.
<b>DA record</b>	'Extra' census record from a duplicate pair – i.e., QualityStage™ has found two census (A) records that match the same mortality (B) record with total weight above the cut-off. One of these census records will be listed as part of a matching pair (MP), and the other as a duplicate match (DA). (The pair with the highest total weight will be listed as MP.)
<b>DB record</b>	'Extra' mortality record from a duplicate pair – i.e., QualityStage™ has found two mortality (B) records that match the same census (A) record. One of these mortality records will be listed as part of a matching pair (MP), and the other as a duplicate match (DB).
<b>Dataset or Database</b>	A large collection of information files, often stored in electronic form.
<b>Decedent</b>	Deceased person.
<b>Disagreement weight</b>	See <b>Weight</b>
<b>Domicile Code</b>	A classification system used by NZHIS to describe geographically based administrative units. Each domicile code refers to an area containing a median population of about 2,000. The NZHIS domicile codes have a one-to-one concordance with SNZ census area units, but (unfortunately) use a different coding system (due to historical limitations in the NZHIS database).
<b>Duplicate pair</b>	Two records from one file which can both form a comparison pair with a single record from the other file, and each comparison pair has a total weight above the cut-off (i.e. both are potential links).

<b>False negative link</b>	A comparison pair that is not accepted as a link, but is in fact a match.
<b>False positive link</b>	A comparison pair that is accepted as a link, but in fact is not a match.
<b>Frequency ratio</b>	The ratio of the probability of variable agreement in a matching pair to the probability of variable disagreement in a non-matching pair – i.e. $m / u$ . The frequency ratio gives a measure of the relative significance of agreement on a particular variable. It is converted to a logarithmic scale for ease of comparison (see <b>Weight</b> ).
<b>Field</b>	The information for each variable as presented in a file. For example, the 'income' field in the census file contains the information for the variable 'income' for each record (or person). In a computerised file, fields are often represented by columns.
<b>File</b>	A collection of multiple records. In the NZCMS, File A refers to census records, while File B refers to mortality records.
<b>Geocode</b>	A code referring to a geographically based unit of administration, forming part of a classification system. Geocodes referred to in this study include area units, domicile codes and meshblocks.
<b>Linkage bias</b>	Systematic differences by socio-demographic factors (e.g. age, deprivation) between linked and unlinked mortality records.
<b>Links</b>	<ol style="list-style-type: none"> <li>1. A comparison pair that is accepted as being highly likely to apply to the same individual. In the NZCMS &gt; 95% of links are probably matches.</li> <li>2. A golf course (i.e. open <b><u>field</u></b>), where <b><u>matches</u></b> are often played with little <b><u>agreement</u></b> between <b><u>pairs</u></b> (&gt;95% of score cards are estimated to be correct, the remaining probably systematically biased)</li> </ol>
<b>MP pair</b>	A linked (probably matching) pair of records, consisting of one census record (A) and one mortality record (B). The total weight for the pair is above the specified cut-off for the given QualityStage™ pass.
<b>m-probability</b>	See <b>Probability</b>

<b>Match</b>	A pair of records that applies to the same individual (i.e. true links).
<b>Match run</b>	The sequence of passes used to link two files of records.
<b>Matching variables</b>	Variables common to two sets of records, for which we determine agreement or disagreement when comparing records.
<b>Meshblock</b>	The smallest geographic area used for coding purposes by Statistics New Zealand, with a median population size of 90-100.
<b>National Health Index (NHI)</b>	An NZHIS dataset, containing data for nearly every individual in New Zealand. This data is collected and updated every time a person uses public health services (e.g. outpatient visits, diagnostic investigations). The NHI dataset can be linked to NMDS events for the same individual by means of a unique identifier (the NHI number).
<b>National Minimum Data Set (NMDS)</b>	A dataset administered by NZHIS. Contains data for most individuals in New Zealand on both hospitalisation events and (where deceased) death events. Unlike the NHI dataset, which is updated for each new event, the NMDS contains a separate record for each hospitalisation event and thus provides several separate records for the same individual.
<b>New Zealand Census-Mortality Study (NZCMS)</b>	The New Zealand Census-Mortality Study (NZCMS) now consists of five cohorts of anonymously, probabilistically linked Census and Mortality records. See this and related documents for further information or look at <a href="http://www.wnmeds.ac.nz/nzcms-info.html">http://www.wnmeds.ac.nz/nzcms-info.html</a>
<b>Non-links</b>	A comparison pair that is <i>not</i> accepted as being highly likely to apply to the same individual.
<b>Non-matches</b>	Pairs of records that do not apply to the same individual (i.e. true non-links)

<b>Partial agreement weight</b>	The process of assigning an intermediate weight to variables that 'almost' agree (e.g. where 'year of birth' differs by only one year). This intermediate weight is less than the agreement weight but greater than the disagreement weight (thus the term 'partial agreement weight').
<b>Pass</b>	The process of linking two files for a given specification of blocking variable, matching variables, $m$ and $u$ probabilities, and cut-off weight. A series of passes carried out on the same two files is called a match run.
<b>Positive predictive value (PPV)</b>	The percentage of linked records that are matches (or 'true links').
<b>Probabilistic record linkage</b>	Record linkage of two (or more) files using the probabilities of agreement and disagreement between a range of matching variables. (This is distinct from deterministic record linkage, which links files on the basis of exact agreement between matching variables.)
<b>Probability</b>	
<ul style="list-style-type: none"> <li>• <b><math>m</math>-probability</b></li> </ul>	The probability that a matching variable agrees, given that the comparison pair in question is a match. This probability generally reflects the accuracy of the recorded data (e.g. if this is 100% accurate for both types of records, the $m$ -probability will always be 1.0).
<ul style="list-style-type: none"> <li>• <b><math>u</math>-probability</b></li> </ul>	The probability that a matching variable agrees, given that the comparison pair in question is a non-match. This probability is generally determined by the likelihood of both records having the same value due to chance.
<b>Random Rounded (RR)</b>	Rounding of numerical values to the nearest multiple of three. Wherever this report refers to a particular group of census records, the total number of records will be random rounded in order to protect confidentiality.
<b>Record</b>	A set of variables applying to a single individual, observation or unit. In a computerised file, records are often represented by rows.

<b>Record Linkage</b>	The process of linking two or more files by looking for agreement or disagreement between matching variables within individual records.
<b>Rejection weight</b>	The total weight set as a threshold for determining which comparison pairs are <i>not</i> accepted as links (i.e. the records are deemed to apply to two different individuals).
<b>QualityStage™</b>	Latest version of the software package for carrying out probabilistic record linkage. The original version used was AutoMatch®.
<b>Sensitivity</b>	The proportion of matches detected as links, i.e. $[\text{true links}] / [\text{matches}]$ .
<b>Skipping</b>	Where two matching records fail to be linked because one of the records has been assigned to the incorrect block (on the basis of an erroneous blocking variable).
<b>Specificity</b>	<p>Using either file in the record linkage process, the proportion of non-matching records detected as non-links, i.e. <math>[\text{true non-links}] / [\text{non-matches}]</math>.</p> <p>Note: a) the specificity varies depending upon which files it is calculated; b) the specificity can also be calculated from the perspective of comparison pairs (as opposed to records).</p>
<b>Total weight</b>	The sum of the agreement / disagreement weights for each matching variable in a comparison pair of records.
<b>True negative link</b>	A comparison pair that is not accepted as a link, and is in fact a non-match.
<b>True positive link</b>	A comparison pair that is accepted as a link, and is in fact a match.
<b><i>u</i>-probability</b>	See <b>Probability</b>

<b>Value-specific weightings</b>	Agreement and disagreement weights that are specific to the actual value of a given variable. Value-specific weightings are used where some values are far less common than others, so the relative significance of an agreement for that value is much greater. For example, the agreement on New Zealand as country of birth adds much less weight than an agreement on Africa.
<b>Weighting</b>	The process of assigning a value to all possible comparisons of matching variables.
<b>Weight</b>	
• <b>Agreement weight</b>	<p>The value assigned for agreement on a given matching variable. This value is a positive number, calculated from the <math>m</math> and <math>u</math> probabilities for that variable according to the following formula:</p> $[\ln (m / u) / \ln(2)].$
• <b>Disagreement weight</b>	<p>The value assigned for disagreement on a given matching variable. This value is a negative number, calculated according to the following formula:</p> $[\ln ( (1-m) / (1-u) ) / \ln(2)].$

## Abbreviations

<b>AU</b>	area unit (median population about 2,000)
<b>CAU</b>	census area unit - i.e. an area unit derived from census data (use area unit as the preferred name)
<b>dd</b>	day of birth
<b>E[FP]</b>	Expected number of false positive links
<b>mm</b>	month of birth

<b>yyyy</b>	year of birth

# Introduction

The primary aim of the New Zealand Census-Mortality Study is to determine mortality rates within different ethnic groups and socio-economic strata of the New Zealand population, and so estimate the association between socio-economic factors and mortality.

This is being undertaken through a series of cohort studies, where the cohort consists of the entire New Zealand population and the follow-up period is the three years following each census. The exposures of interest are ethnicity and socio-economic factors, and the outcome of interest is death in the three years following census night. Thus, in calculating mortality rates, the numerator (number of deaths) is derived from mortality data linked to census data, while the denominator (population number) is derived from census data.

If socio-economic factors were included on mortality records, it would be possible to calculate stratified mortality rates using unlinked census and mortality data. Unfortunately this is not the case: detailed socio-economic data (including education, labour force status, car access, housing tenure and household income) is included in census records, but not in mortality records. Therefore, the only way to calculate stratum-specific mortality rates is to link each mortality record back to its corresponding census record. This allows us to unite each decedent's mortality record with the socio-economic data recorded on the corresponding census form, and so assign each death event to the appropriate socio-economic stratum.

Further, the NZCMS allows us to check (and correct if necessary) any differences in the recording of ethnicity between census and mortality data, therefore ensuring accurate mortality rate calculations by ethnic group.

This report focuses on linking mortality records to the 2001 census data, and draws on the knowledge already gained by the team in linking four previous census cohorts to mortality data (Hill et al, 2002). Mortality data has previously been linked to 1981, 1986, 1991, and 1996 census data. Details of these earlier linkage processes can be found in reports on the Wellington School of Medicine and Health Science web site.

The objectives of this report are:

1. To describe the linkage methods, data requirements, linkage process, linkage outputs, and main analytical files for the 2001-04 cohort in the New Zealand Census-Mortality Study (NZCMS)
2. To describe the calculation of weighting factors to adjust for *linkage bias* in the 2001-04 Cohort in the NZCMS.
3. To describe the calculation of '*unlock ratios*' to adjust for any undercounting of Māori and Pacific deaths in the New Zealand mortality records, for the period 2001-04.

The report is organised in three parts, each addressing one of the above objectives.

By linkage *methods* we mean the anonymous and probabilistic record linkage methodology; and the methods developed in the NZCMS to determine the accuracy of the linkage. By *data requirements* we mean the preparation of mortality and census files for linkage, including descriptions of the necessary variables and geocodes.

By linkage *process* we mean the steps we undertook to link the 2001 census to mortality data, including the estimates of linkage accuracy.

By linkage *outputs* we mean the three files directly arising from the record linkage (linked census-mortality records, residual mortality file and residual census files), including the numbers of records in each file.

By *main analytical files* we mean the bias, unlock, and cohort files for the 2001 cohort.

- The bias file for the 2001 cohort consisted of all eligible mortality records, with an indicator variable for whether the mortality record was linked to a census record. This bias file allowed us to determine the differences in demographic and other characteristics between those mortality records linked and unlinked (i.e. *linkage bias*).
- The unlock file consisted of the subset of highly probable linked census-mortality records. We have used this file to determine the discrepancy between ethnicity recorded on census versus mortality data (i.e. unlocking the so-called numerator-denominator bias that has affected all routine calculations of mortality rates by ethnicity in New Zealand).
- The cohort file consisted of the full census file with information on mortality for those census records linked to a mortality record. (The cohort file has been weighted to adjust for linkage bias.) The cohort file is the major analytical file in the NZCMS that is and has been used for the majority of research outputs.

By *linkage bias* we mean that as the success of the linkage varies by socio-demographic strata, a consequence is that the association between socio-demographic measures and mortality outcome may be biased. Inverse probability weights are used to adjust for linkage bias.

By *unlock ratios* we mean the adjustment ratios used to adjust for numerator denominator bias in the calculation of un-linked ethnic specific mortality rates. This bias arises because the method of collecting and recording ethnicity data on the census and mortality records is different. Thus when mortality rates are calculated by dividing strata specific mortality counts by population counts for the same strata the results may be biased, because individuals are counted in different strata on the numerator and denominator. Changes made, in September to December 1995, to the way that ethnicity is recorded on the death registration form considerably reduced this bias. Nevertheless the unlock ratios were calculated to monitor the effectiveness of these changes. (Ajwani et al. 2002; Ajwani et al. 2004; Ajwani et al. 2003)

A significant difference between the 2001 cohort and the previous four cohorts is the age group used. The 2001 cohort includes all ages instead of just 1-74 years as used in the previous four cohorts. Previously, those older than 74 years on census night were excluded for two reasons; a concern that mobility into residential care would adversely affect the linkage; and a presumption that social group differences in mortality were not 'large' among the elderly. Recent research, combined with an aging population, means that we now include these older people in the 2001-04 linkage.

This report continues the series of technical reports describing the establishment of the first four cohorts of the NZCMS. This report combines for the 2001-04 cohort the elements that were reported in three separate reports for the earlier cohorts.(Ajwani et al. 2002) (Fawcett et al. 2002; Hill et al. 2002)

# Part I Record Linkage for 2001-04 Cohort

## I.1. Methods

A brief summary of the method for the anonymous linkage of census and mortality files is provided below. Readers interested in a more detailed description of the method should refer to previously published Technical Reports (Ajwani et al. 2002; Blakely 2001; Blakely et al. 1999) (Fawcett et al. 2002; Hill et al. 2002). These reports are available on the NZCMS website (<http://www.wnmeds.ac.nz/nzcms-info.html> or full path of <http://www.wnmeds.ac.nz/academic/dph/research/HIRP/nzcms/index.html>).

### I.1.1 Summary of Methods for the Anonymous Linkage

The goal of the anonymous and probabilistic linkage process is to link two files containing records for the same population, but without the benefit of unique identifying variables to aid the linkage.

Hence we started with two sets of records: File A and File B. Each file contained records relating to the same population. File B consisted of mortality records from a three year period, and File A consisted of records from the census immediately preceding that period. Thus (in theory) each record in File B had a corresponding record (belonging to the same person) in File A.

Therefore, the purpose of probabilistic linkage was to match the records in File A to the most likely matching record in File B.

**Figure 1: File A (census records) and File B (mortality records)**

Probabilistic linkage applies a formalised system to the intuitive process of looking for agreement and disagreement between two individual records, and weighting the value of those agreements and disagreements to choose the most likely match.

Probabilistic record linkage combines two processes:

- It looks for agreement or disagreement between the corresponding (matching) variables contained in two records (**record linkage or matching**).
- It assigns relative significance to each agreement/disagreement on the basis of probabilities (**weighting**).

The NZCMS is based on probabilistic record linkage using **QualityStage™** software. This has superseded Automatch®, the software package used for the linkage of the earlier cohorts.

### **I.1.2 Blocking**

To increase the computational efficiency of the record linkage, files were compared within **blocks**. A block is a subset of data within which the value of the **blocking variable** is the exactly the same on both files.

**Figure 2: Blocking**

For matches to be found, the blocking variable must be correct as comparisons between Files A and B only occur within the blocks. If this is not the case then the record cannot be linked. This problem is known as **skipping**. To avoid skipping, records not matched within the first block comparison were pooled together, and submitted for matching with a second blocking variable. This process was repeated several times, using a different blocking variable for each matching process. Each time the number of unmatched records remaining became smaller, until eventually the marginal return was negligible. A single matching process (using one blocking variable) is called a **pass**. The sequence of passes used to match two sets of records is known as a **match run**.

### I.1.3 Weights

Matching has greater significance for some variables than for others. For example, agreement on sex has relatively little significance, whereas agreement on date of birth has more significance. In probabilistic linkage, difference in the significance of matching by different variables is accounted for by assigning weights to the different variables being matched.

The ***m probability*** is the probability of agreement for a given variable between two records for the same individual (i.e. a matching pair). The ***u probability*** is the probability of agreement between records for two different individuals (i.e. a non-matching pair).

The ***m probability*** depends upon the accuracy of the recorded data. For example, if day of birth is incorrectly recorded in 5% of records, the *m* probability for day of birth will be 0.95.

The *u* probability depends mainly on the likelihood of a variable matching due to chance. For example, a person's day of birth will be one of 31 possibilities. Thus the likelihood of a match for day of birth between two different individuals is 1/31 or 0.032.

The **agreement frequency ratio** is the ratio of the  $m$  and  $u$  probabilities. The frequency ratio provides a measure of the relative significance of agreement between variables for a particular variable. Agreement frequency ratios range from 1 to  $+\infty$ .

**Disagreement frequency ratios** can also be calculated for *disagreement* between two variables (i.e.  $[1-m]/[1-u]$ ). This gives a measure of the relative significance of a non-match for this variable. Disagreement frequency ratios range from 0 to 1.

For ease of use it is conventional to convert these ratios to a linear scale using the natural logarithm to base two. The use of base two logarithms means that agreement ratios are expressed as positive numbers, while disagreement ratios are expressed as negative numbers. The base two log is the *relative probability of a true match*, where positive numbers represent increasing probability and negative numbers represent decreasing probability. The *relative probability of a true match* is called the *weight*.

**Table 1: Example of agreement and disagreement frequency ratios and weights for comparison by matching variable 'day of birth'**

Comparison Outcome	Proportion Links	Non-links	Frequency ratio	Weight
Agreement	0.95 ( $m$ )	0.03 ( $u$ )	32/1 ( $m / u$ )	4.98 $[\ln(m / u) / \ln(2)]^{\dagger}$
Disagreement	0.05 ( $1-m$ )	0.97 ( $1-u$ )	1/19 ( $(1-m) / (1-u)$ )	-4.28 $[\ln((1-m)/(1-u)) / \ln(2)]^{\dagger}$

<sup>†</sup> The divisor,  $\ln(2)$ , transforms the natural logarithm to a base 2 logarithm.

For each comparison pair, weights were calculated for each variable by the above process. The weights for each variable were added together to give a *total weight* for this comparison pair. This total weight indicates the relative probability that the two records belong to the same individual.

QualityStage<sup>TM</sup> undertook the mechanical aspects of the weighting and linkage processes described above. However, we first had to specify the  $m$  probability and other particulars of the matching process to be used for each variable. Details of these specifications are in the Technical Report for the 1991 Census Cohort.(Blakely et al. 1999)

### I.1.4 Determining Cut-Off Weights

Weights were calculated for all possible pairs in a block. Where the variables matched for all variables, the matching pair had a highly positive weight. Conversely, where there was no agreement for any of variables (non-matching pair) the pair was assigned a highly negative weight. There were many more non-matching pairs than matching pairs and so the distribution of the total weights for two sets of records was generally bimodal (see Figure 3). Some pairs had a total weight in the intermediate range indicating a match for some variables, but not for others. A number of these pairs represented true links, while others represented false links.

**Figure 3: Distribution of matching and non-matching pairs by total probabilistic weight**

The *total weight* was used as the basis of the decision to accept or reject pairs as links. The cut-off threshold is a trade-off between the *number* and the *accuracy* of the links obtained. A higher threshold means that pairs are accepted only if they are highly likely to be true links. This approach gives a smaller number of links. Adopting a lower threshold means that many more pairs are accepted as links, but a number of these are likely to be false links (see Section I.2 below).

Clerical review may be used to improve both the accuracy and the yield of our linkage where pairs with intermediate weights are reviewed manually. However, for 2001-04 we used various decision rules conducted in SAS, rather than clerical review per se.

### I.1.1 Improving Discriminatory Power

With QualityStage™ a number of techniques can be used to improve the discriminatory power of the linkage: In particular the use of value-specific weightings, partial agreement weights and arrays.

*Value-Specific Weightings* assign different weightings to specific *values* for the same variable. For example, a birthplace of 'Australia' is relatively common amongst New Zealand residents; thus a match for this variable (due to chance) is far more likely than for the birthplace grouping 'Africa'. A match on country of birth for the grouping 'Africa' has more weight than a match for the value 'Australia'. In the NZCMS, specific *m* and *u* probabilities were particularly relevant for the variables of ethnicity and country of birth.

*Partial Agreement weights:* Sometimes numerical variables are very close to agreeing, and differ by only a single digit. For example, it is common for the year of birth to be reported and entered incorrectly by only one or two years. Hence a small disagreement in year of birth is less significant than a large disagreement. Partial agreement weights allow a matching with specified degree of variation (or tolerance) in the numerical values on the two files. In these cases the weight applied for that variable is the partial agreement weight, which is a proportion of the full agreement weight. For example, in this study, a mismatch by one year, on the year of birth variable, was assigned a weight nearer to the agreement weight than a mismatch of two years. For the 2001-04 linkages 'tolerances' of plus or minus one were applied for day of birth and year of birth, for some later passes only.

*Arrays:* QualityStage™ allows variables to be specified as arrays. An array is a set of alternative values for the same variable. For example, the mortality data includes dates of birth from more than one source, and occasionally these sources differed. At least one of these values should have been incorrect, but we had no way of determining which was the true date of birth for that person. By specifying each of day, month and year of birth as three arrays, the alternative values were utilised to improve the probability of linkage.

### I.1.5 Quality Shage™ Terminology

The NZCMS used two files for each census cohort. File A consisted of all census records. File B contained of mortality records for all people for the three years following the census. Theoretically, every record in File B should

have had a corresponding record in File A. However, in practice there are some mortality records for which there is no corresponding census record. For example where the decedent was not in New Zealand on census night or did not fill out a census form.

All comparison pairs were assigned to one of three categories

- Where the total weight was above the chosen threshold for a true link the pair was designated a matched pair (MP)
- If two census records matched to a single a single mortality record, both with probability weights over the threshold, the pair with the highest weight was designated 'MP', and the remaining census record was designated 'DA' (duplicate A). If both pairs had the same weight one was arbitrarily assigned as 'MP' and the other as 'DA'.
- Less commonly, two mortality records could have been matched with the same census record. Again, the pair with the highest weight was designated 'MP', and the remaining mortality record categorised 'DB' (duplicate B).

In practice, around three-quarters of all mortality records were successfully matched with a census record and accepted as links in the 1980's and 1990's. In contrast, only a very small proportion of individuals who completed census forms were be expected to die in the following three years. Thus the vast majority (~99%) of census records remained unlinked at the end of the linkage process.

## I.2. Determining the Accuracy of the Record Linkage

The nature of anonymous and probabilistic linkage means that we cannot be entirely certain that a linked pair of records do actually belong to the same person. Mortality records can be distributed according to link/non-link status by match/non-match status as illustrated in the two-by-two table below. If the outcome was death, then matches would be those who died during follow-up and non-matches would be those alive at the end of follow-up.

	Matches	Non-matches
Linked	<b>a</b> (true positives)	<b>b</b> (false positives)
Unlinked	<b>c</b> (false negatives)	<b>d</b> (true negatives)

In probabilistic record linkage this categorisation is achieved by setting a cut-off score above which comparison pairs are considered linked, and below which they are considered unlinked. The higher the cut-off, the more probable the link is to be a match. Accordingly, we can quantify the performance of the record linkage in *classifying the outcome* in the following way:

Sensitivity	$= a / (a+c)$
Specificity	$= d / (b+d)$
Positive predictive value	$= a / (a+b)$
Negative predictive value	$= d / (c+d)$

These parameters will vary depending on the cut-off: Decreasing the cut-off will increase the sensitivity, but also increase the number of false positives; Increasing the cut-off will decrease the sensitivity, but also decrease the number of false positives.

Since we have no 'gold standard' for establishing which matches are true links, we used indirect measures to estimate the sensitivity and specificity of our linkage process.

The *sensitivity* of our record linkage was estimated from the proportion of mortality records that were successfully linked in the final match run – i.e.:

$$\text{Sensitivity} = \frac{\text{Number of mortality records that were successfully linked (a)}}{\text{Number of mortality records for which a link is possible (a + c)}} \approx \frac{\text{Accepted links}}{\text{All true links}}$$

This estimation is based on two assumptions:

1. The number of false positive links is negligible compared with the total number of accepted links .
2. The number of mortality records for which there are no corresponding census records is negligible .

There is no corresponding simple approximation for estimating the *specificity* of record linkage. The specificity varies depending on whether it is calculated from the perspective of the mortality or census records. Unlike the sensitivity, the specificity cannot be directly estimated from the numbers of records linked.

Two methods ('chance method' and 'duplicate method') for estimating the PPV were developed specifically for the NZCMS. Details of these can be found in the first Technical Report (pages 43-61) and elsewhere.(Blakely 2002; Blakely and Salmond 2002; Blakely et al. 1999) Both methods are applicable only to record linkage projects where there is only one true link for each record (so-called 'best linkage').

The chance method estimates the number of false positive links among exactly matching pairs. For example, on average there are about ([sex (2)] × [dd (30)] × [mm (12)] × [yyyy (60)] × [ethnicity (1.2)] × [country of birth (1.2)] = 10,368) 10,000 possible combinations of exact agreements.<sup>1</sup> Thus, each mortality record has an approximately 0.00001 probability of agreeing exactly with any *one given* census record. For a meshblock pass where each mortality record is compared to 100 census records, each mortality record has a 0.001 or 0.1% chance of forming a false positive link.

The duplicate method utilises the varying probability of a false positive link by total weight score in the record linkage and the occurrence of duplicate links. Its main advantage over the chance method is its applicability to non-exact agreements. Using the probabilities of a single mortality record being matched

---

<sup>1</sup> Where 60 for year of birth and 1.2 for ethnicity and country of birth are 'weighted' numbers given the uneven distribution by values for these variables.

with zero, one, or two census records, it estimates the number of false positive links using binomial combinatorial probabilities. This method is described in detail elsewhere.(Blakely and Salmond 2002)

Each of the above methods has advantages and limitations. In practice, both were used and produced similar results in earlier cohorts and indicated an overall PPV of around 97.5 – 98% for all record linkage.

### **I.3. Data used in the record linkage**

This section focuses on the creation of census and mortality data files with variables that were suitable for the linkage. A detailed description of all the variables that were available on the three NZCMS 2001-04 datasets is provided later (Section I.5).

#### **I.3.1 Census Data**

All census data is stored by Statistics New Zealand, and is kept under conditions of strict privacy. Since the data was not permitted to leave SNZ, SNZ undertook both the preparation of the census files, and the actual record linkage. The census data required for the NZCMS 2001-04 cohort was extracted from the census master-file and made into a new file with the few variables that were needed for the linkage.

#### **I.3.2 NZCMS Census Linkage File**

Variables included in the census file were those that were to be used for integrating with mortality files (i.e. record linkage). The census variables that were used in the record linkage are presented in Table 2. (The full list of all census variables available for the cohort analyses is presented in Table 52, page 113). A more detailed description of the derivation of all variables used for the linkage is given in section I.5 (page 47).

**Table 2: Census variables included for use in record linkage**

Group	Variable Names	Format.	Notes
Unique Identifier	ID	\$8	Unique Identifier on Census
Geocoded variables	AU	\$6	Area Unit (Usual Residence base 2001)
	MB	\$7	Meshblock (Usual Residence base 2001)
Country of birth	COB	F9bthgp.: 1=NZ, 2=Australia, 3=British Isles, 4=Europe, 5=Pacific Is, 6=Africa, 7=Americas, 8=Asia, 9=Elsewhere, 0=Missing	Country of Birth Group
Date of Birth	DAYA	1 to 31 or 99 for missing	Day of birth
	MONTHA	1 to 12 or 99 for missing	Month of birth
	YEARA	1900 to 2001 or 9999 for missing	Year of birth
Sex	SEX	1=Males, 2=Females	Sex
Ethnicity Variables	MAORI	1=NZ Maori, 0=not Maori, 9=missing	Maori : non-Maori total ethnicity
	PACIFIC	2=Pacific People, 0=not Pacific, 9=missing	Pacific : non-Pacific total ethnicity
	ASIAN	4=Asian, 0=not Asian, 9=missing	Asian : non-Asian total ethnicity
	NONMPA	5=nonM nonP nonA, 0=Maori or Pacific or Asian, 9=missing	non-Maori, non-Pacific, non-Asian ethnicity
Country of Birth and Ethnicity Interaction Variables	PACFIX	2=Born in Pacific and Pacific Ethnicity on Census, [5=Born in Pacific and Pacific Ethnicity on Mortality], 9=Not born in Pacific and/or not of Pacific Ethnicity	Pacific born and Pacific ethnicity

Group	Variable Names	Format.	Notes
	ASNFIX	4=Born in Asia and Asian Ethnicity on Census, [8=Born in Asia and Asian Ethnicity on Mortality], 9=Not born in Asia and/or not of Asian Ethnicity	Asian born and Asian ethnicity

NonMPA = non Maori, non Pacific, and non Asian.

The country of birth and ethnicity interaction variables denoted Pacific and Asian people born in the Pacific or Asia respectively and was necessary to prevent “double counting” for these people, leading to a too high agreement weight and some linkages that were not correct. (I.e. As both Pacific or Asian ethnicities are relatively uncommon in the data and Born in Pacific or Born in Asia are also relatively uncommon in the data, they both have high probability weights and if someone has both Pacific ethnicity and Born in the Pacific they will have both these weights added and this total weight needs to be reduced to make sure other variables used in the linkage also agree.)

## I.4. Mortality Data

A file of records for decedents who died in the three years subsequent to the 2001 census was created from five data files provided by the New Zealand Health Information Service (NZHIS). These five files contained a subset of data from the Current National Hospital Index dataset (NHI), December 2001 Archive of the NHI dataset, the National Minimum Data Set (NMDS), Mortality Events file and the Mortality Diagnostics File.

In order to create a file suitable for linking with the census, it was necessary to create a Mortality Linkage File. This included variables from all five of the above data files.

The Mortality Linkage File was restricted to those who were alive on census night. Decedents whose domicile was coded as overseas were also excluded. Some further records were deemed ineligible if the decedent was unlikely to have been resident in New Zealand at the time of the census.

Ideally, we wished to exclude any New Zealand resident who died in New Zealand but had not been living in the country at the time of the 2001 census (since their mortality record would have no corresponding census record and thus could not be linked). The NMDS mortality database includes a 'duration in New Zealand' variable, recording how long each decedent has been living in New Zealand. Experience from the linkage of earlier NZCMS cohorts had shown that on the majority of mortality records the 'duration in New Zealand' variable was filled in with what seemed to be age at death.

Despite this, there were, three groups for whom linkage was very unlikely.

1. Children under (or exactly equal to) 3 years of age, whose duration value was less than their age. (186)
2. Decedents with a value of zero for their duration in New Zealand field. (101)
3. Decedents whose duration in New Zealand was less than the time between their death and census night, and the value is not blank or 99 or zero, nor is it equal to their age. The data suggested that the decedent did not live in New Zealand at the time of the 2001 census. (232)

#### **I.4.1 NHI-Current File (82640 mortality records for the 2001-04 cohort)**

The National Hospital Index (NHI) file holds demographic information for each person who comes in contact with the public hospital system. The data is updated each time an individual uses the public health system. Historical data is currently not retained.

Information contained in the NHI-Current file includes date of birth, date of death, ethnicity codes, a unique NZCMS ID number, domicile code (equivalent to census area unit), address flag and geocoded meshblock. The file includes one record per decedent.

#### **I.4.2 NHI-Archive File (81958 records for the 2001-04 cohort)**

The personal information on the NHI dataset is updated each time a person comes in contact with the hospital system; consequently the historical data is over-written. In anticipation of linking the 2001 census, an archive file of the NHI file was made by NZHIS in December 2001. The address information on this dataset is that held at the time the archive file was created. Where individuals changed address between December 2001 and their date of death, the geocoded address (meshblock) information was different than that stored on the current NHI dataset file.

The historical dataset thus provides alternative values for all variables on the NHI\_current file. This was used for creating the Mortality Linkage File. However, because the file is only updated when a person has contact with the hospital system the archive file may not necessarily contain more up-to-date information than the mortality file. Fortunately the date of contact with the hospital system is recorded. In general the value of most variables used in the linkage process was the value recorded closest to the census date.

#### **I.4.3 National Minimum Data Set (NMDS) Subset (502539 records)**

The NMDS subset contains records for a number of health events (hospitalisation, cancer registrations etc...) relating to any one person who subsequently died. The dataset has one record per health event. The file for the NZCMS included sex, date of birth, date of death, dates of admission, dates of discharge, ethnicity codes, New Zealand resident status, country of birth, domicile codes, address flag and a unique NZCMS ID number.

The NZCMS ID numbers were created and used for linking the different mortality data sets. It is noted however, that individual NHI numbers were unknown to us, helping to ensure that confidentiality was maintained.

#### **I.4.4 Mortality Event File (82640 records for the 2001-04 cohort)**

The mortality file is derived from death certificates (form BDM50) and includes one record per decedent. The information includes date of birth, date of death, unique NZCMS ID number, ethnicity codes, country of birth, years in New Zealand, domicile codes, geocoded address (meshblock), Death type codes, clinical notes related to the death, and occupation codes.

Regarding the NMDS death event, it is important to note that the demographic details (date of birth, sex, ethnicity and country of birth) are usually entered independently of the NHI file. The information is elicited by an undertaker and entered on the death registration form (BDM28). The only situation in which NHI and NMDS data are derived from the same source is when a decedent has no previous hospitalisation event, in which case the NMDS demographic data is used to construct the NHI file.

#### **I.4.5 Mortality Diagnostics file (121514 records- death events)**

The mortality diagnostics file included cause of death information for both the underling and contributing causes of death. There was a separate record for each cause of death, so each decedent may have multiple records. The unique NZCMS ID number identifies decedents. Variables on the file include id, diagnostic type, clinical code and clinical coding version used.

#### **I.4.6 Creation of the NZCMS 2001 Mortality Linkage File<sup>2</sup>**

The NZCMS 2001 Mortality Linkage file was created by combining four files:

1. The NHI–current file
2. The NHI–archive file
3. The National Minimum Data Set subset
4. The Mortality Event File

Note that cause of death information was not included on the NZCMS Mortality Linkage file. Cause of death data was merged with the NZCMS 2001

---

<sup>2</sup> \2001\_04\SASforLinkage\alldataforlinkage.sas7bdat

MASTERFILE after the linkage of census and mortality records was completed (see Figure 4).

The creation of the mortality linkage file from four files had several important implications:

**Mortality records sometimes contained more than one value for certain variables (i.e. date of birth, sex, ethnic group).** This occurred where variables were recorded independently on different files. For example, variables could differ between files for the same individual for changing self-defined ethnic group over time, or coding errors for date of birth.

A systematic approach was developed to create the variables that were used in the record linkage. The derivation of each variable from the multiple sources of information is described in the following sections.

**Several sources of information for the geocoded address fields were included in each mortality record.**

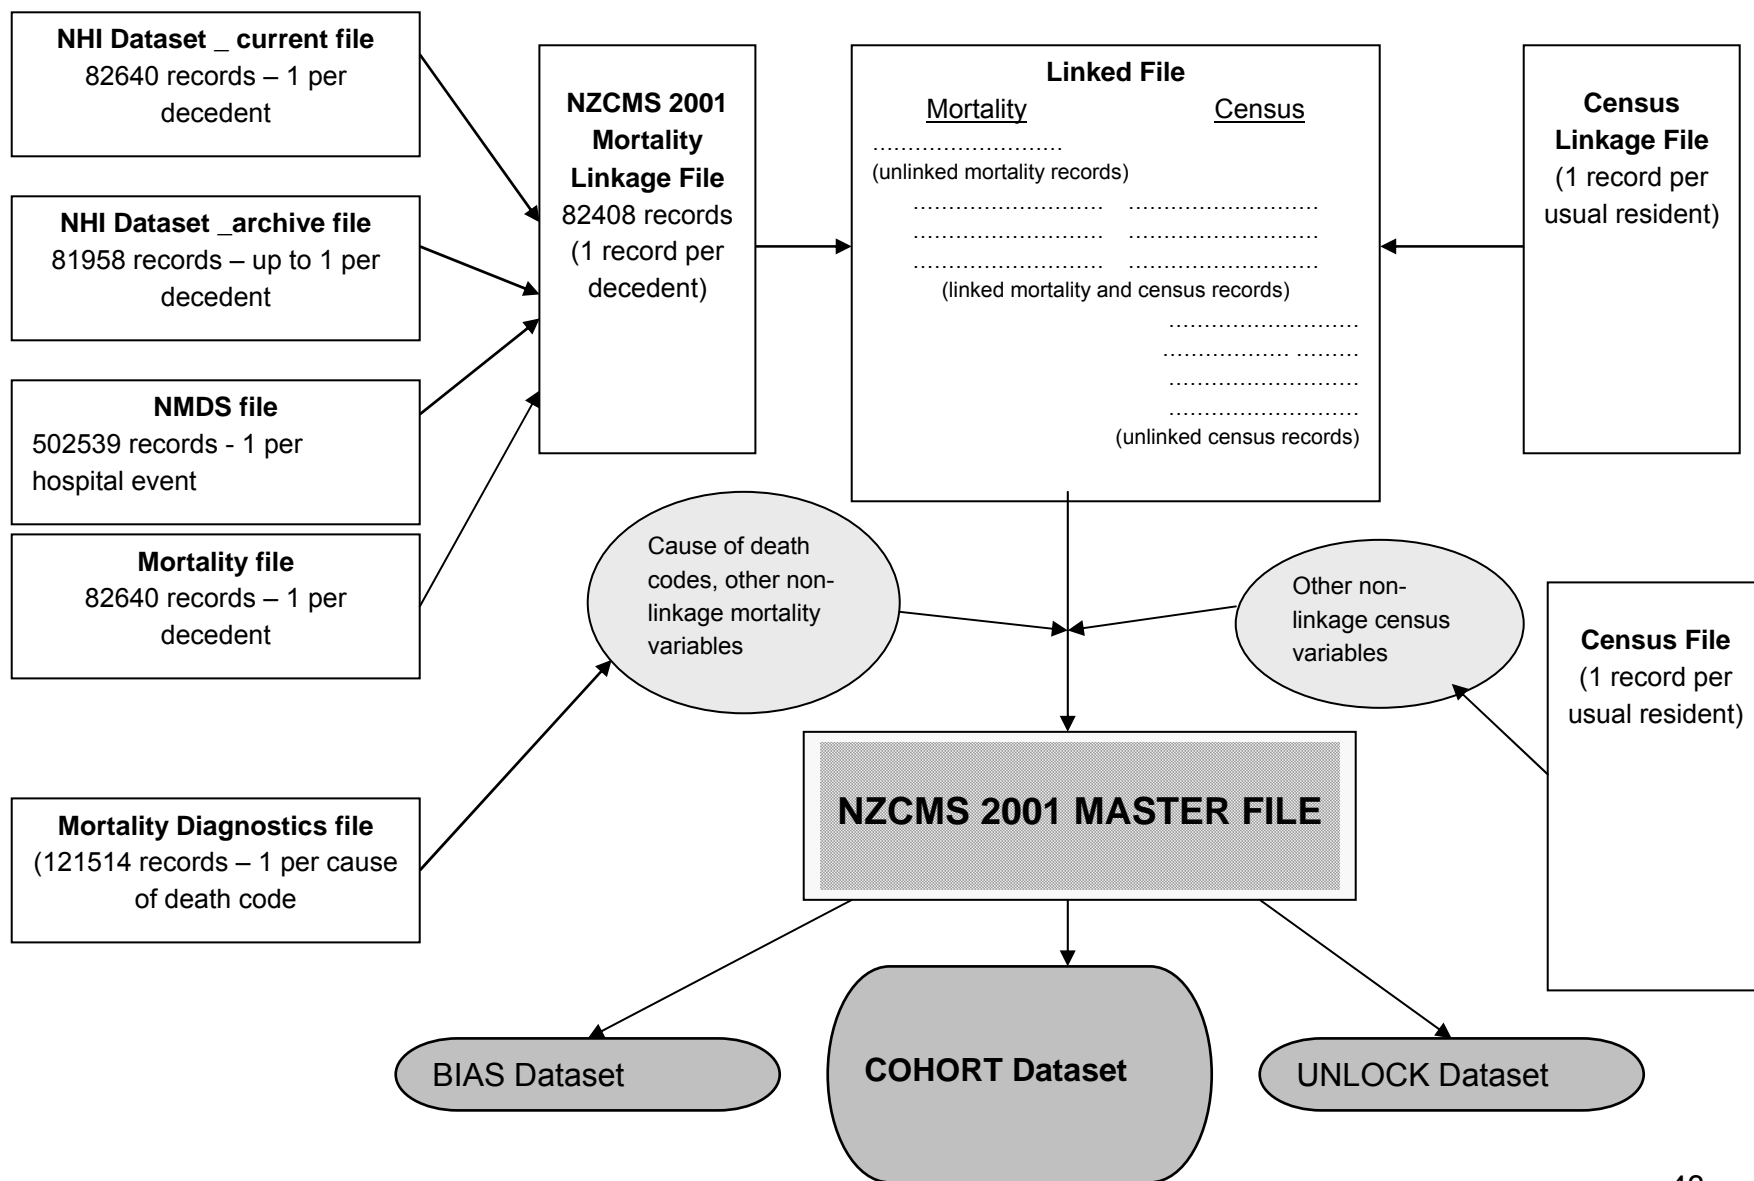

Two types of geocoded data were used to create blocking variables for the data linkage – Meshblocks and Area Units.

The smallest administrative unit used by SNZ is the ‘meshblock’, which have a median population of about 100 people. Meshblocks are nested within ‘area units’ (AU), which have a median population of about 2,000. On the census file, each person is coded as residing in a particular meshblock. To assign a meshblock requires detailed information about residential address. The NHI-current file, NHI-archive file and the Mortality event file contained meshblock codes created by NZHIS from detailed address information.

Domicile codes are the NZHIS equivalent of SNZ Area Units (AU). Several domicile codes (or area units) are available for any one individual: two from their current and archived NHI record, and one from *each* of their NMDS health event records. The NHI domicile code is that entered directly by a hospital at a person’s last health event. NMDS domicile codes correspond to a person’s address at the time of various health events.

Figure 4 gives a diagrammatic representation of the creation of the various datasets. The variables included on the NZCMS Mortality Linkage file are given in Table 3.

**Figure 4: Sources of Data for the NZCMS Master File (2001-04)**

**Table 3: Variables on the NZCMS 2001 Mortality Linkage File<sup>†</sup>**

Group	Variable Names	Format.	Notes*
Unique Identifier	ID_Mort	\$8.	Unique Identifier
Geocoded variables	*AU1--AU18	\$6.	Area Unit. Up to 18 options in descending order of time near census data, or descending likelihood
	NumAUs	1 to 18	Number of Area Unit Values
	MB01_1 -- MBO1_3	\$7.	Meshblock for linkage, Options 1-3
	NumMB	0 to 3	Number of Meshblock Values
Country of birth	*Bcountry	F9birthgp. : 1=NZ, 2=Australia, 3=British Isles, 4=Europe, 5=Pacific Is, 6=Africa, 7=Americas, 8=Asia, 9=Elsewhere, 0=Missing	Country of Birth
	Bcountry1 - BCountry3	F9birthgp. (See above)	Alternative County of Birth Options 1 to 3
Date of Birth	dob_1 -- dob_5	Ddmmyy10.	Date of Birth options 1 to 5
	*dob_dd1 -- dob_dd5	1 to 31 or 99 for missing	Day of birth options 1 to 5
	*dob_mm1 -- dob_mm5	1 to 12 or 99 for missing	Month of birth options 1 to 5
	*dob_yy1 -- dob_yy5	1892 to 2001 or 9999 for missing	Year of birth options 1 to 5
Sex	SexFlag	fsexflg.: 1=All Same Sex, 2=Mainly one sex + "Other", 3=Mixture of Sexes. Over 67% Male, 4=Mixture of Sexes. Over 67% Female, 5=Unsure of correct sex code, 6=Unsure of Sex. Used Mortality.	Flag to identify records with non-consistent sex values
	*SexforMerge	fvsex.: 1=Males, 2=Females	Sex value for matching
Ethnicity Variables	Eth_A	0 to 46	Number of times identified as Asian
	Eth_A_CNHI	4=Asian, 0=not Asian, 9 (or ) for missing	Asian on NHI file

Group	Variable Names	Format.	Notes*
	Eth_A_Mort	4=Asian, 0=not Asian, 9 (or .) for missing	Asian on Mortality File
	Eth_M	0 to 947	Number of times identified as Maori
	Eth_M_CNHI	1=Maori, 0=not Maori, 9 (or .) for missing	Maori on NHI file
	Eth_M_Mort	1=Maori, 0=not Maori, 9 (or .) for missing	Maori on Mortality File
	Eth_O	0 to 707	Number of times identified as Other
	Eth_O_CNHI	5=nonM nonP nonA, 0=Maori or Pacific or Asian, 9 (or .) for missing	Other on NHI file i.e. nonMaori nonPacific nonAsian
	Eth_O_Mort	5=nonM nonP nonA, 0=Maori or Pacific or Asian, 9 (or .) for missing	Other on Mortality File
	Eth_P	0 to 695	Number of times identified as Pacific
	Eth_P_CNHI	2=Pacific, 0=not Pacific, 9 (or .) for missing	Pacific on NHI file
	Eth_P_Mort	2=Pacific, 0=not Pacific, 9 (or .) for missing	Pacific on Mortality File
	EthTotobs	0 to 947	Total number of ethnicity values
	MultEthCnt	0 to 3	Identifies with more than one ethnic group
Country of Birth * ethnicity Interaction Variables	EthAsianCNHIFix	8=Born in Asia and Asian Ethnicity on NHI, 9=Not born in Asia and/or not of Asian Ethnicity	
	EthAsianFix	[4=Born in Asia and Asian Ethnicity on Census,] 8=Born in Asia and Asian Ethnicity on Mortality or NHI, 9=Not born in Asia and/or not of Asian Ethnicity	
	EthAsianMortFix	8=Born in Asia and Asian Ethnicity on Mortality, 9=Not born in Asia and/or not of Asian Ethnicity	
	EthPacCNHIFix	5=Born in Pacific and Pacific Ethnicity on NHI, 9=Not born in Pacific	

Group	Variable Names	Format.	Notes*
		and/or not of Pacific Ethnicity	
	EthPacFix	[2=Born in Pacific and Pacific Ethnicity on Census,] 5=Born in Pacific and Pacific Ethnicity on Mortality or NHI, 9=Not born in Pacific and/or not of Pacific Ethnicity	
	EthPacMortF	5=Born in Pacific and Pacific Ethnicity on Mortality, 9=Not born in Pacific and/or not of Pacific Ethnicity	

\*matching or blocking variables for the linkage process

†the file includes variables used for QualityStage™ Linkage and for clerical review.

## **I.5. Notes on Specific Variables**

### **I.5.1 Sex Variables**

One sex variable exists for each respondent on the census file. It is never missing as it always imputed by SNZ on the census master file, even if missing from the census form. A flag showing that sex was imputed was included. Imputation was done using information from other members of the household, where the nature of the relationship to the respondent was sufficient that the sex variable could be derived.

All the mortality files included a value for the sex variable. The value of the sex variable (Sexformerge) used for the linkage was derived from the most common value for the variable, or when unsure the value used was the value on the Mortality Events file. The sexformerge variable has no missing values.

An additional variable (SexFlag) was added to the mortality linkage file for use in clerical review. 'Sexflag' was assigned the values: 1=all one sex; 2 = mainly one sex + other; 3 = over 67% values = males; 4 = over 67% values = females; and 5 = unclear, used NMDS sex.

This SexFlag variable was used in clerical review. Sex\_mort was added for the final datasets, this was the actual sex on the mortality file.

### **I.5.2 Date of Birth Variables**

On the census file, data includes one date of birth field. For the linkage, day, month and year of birth were coded as separate variables.

On the mortality file there were up to five date of birth values split into separate variables of day, month, and year. In most cases the date of birth variable was identical on all files. Where values differed, the options were ordered according to how frequently they occurred (i.e. option 1= most frequent date of birth). For the linkage, the day, month and year of birth were coded as separate variables, each with up to five options.

Note that there were up to five different date of births (dd/mm/yyyy) and these were split into their separate variables day, month and year even if this meant they contained the same value. They were not reduced just to unique days, unique months or unique years.

### **I.5.3 Ethnicity Variables**

The census allows individuals to identify with multiple ethnic groups, and since 1995 the death registration form has also allowed multiple ethnic groups to be identified.

For the purposes of linkage, ethnicity was categorised in the following way. Four categories of ethnicity were produced – Maori, Pacific, Asian and NonMPA (European/Other). A series of variables were then created with binary values. For each of the four ethnic groups a variable was used to describe whether the decedent was recorded as identifying with that ethnic group in the various data sources. Where respondents had elected multiple ethnic groups they were coded 1 for Maori, 2 for Pacific, 4 for Asian or 5 for nonMPA for each of the relevant variables corresponding to those options, otherwise they were coded 0, or 9 for missing.

For example.

On the census linkage file one variable (Eth\_M\_Cen) describes whether the respondent was recorded as Māori. Eth\_M\_Cen is coded as 1 if the respondent is recorded as Māori, and otherwise coded as 0 or (9 if missing). Similarly, the respondent is coded as 4 or 0 for Asian (Eth\_A\_Cen), as 2 or 0 for Pacific (Eth\_P\_Cen), and as 5 or 0 for other (Eth\_O\_Cen) ethnic groups. Ethnicity was missing for 3.8% of census records.

Corresponding variables were created on the mortality files. The mortality linkage file also included variables for ethnicity from the NHI files. For example, Eth\_M\_Mort was coded 1 if Māori on NMDS Mortality File, otherwise coded as 0. Eth\_A\_CNHI looked at the data on both the NHI Current file and the NHI Archive files and chose the value of the variable dated closest to the 2001 Census. It was then coded 1 if Māori, 0 if other, or (9 if missing).

The same process was used to create similar variables for the Asian (Eth\_A\_CNHI, Eth\_A\_Mort, Eth\_A), Pacific (Eth\_P\_CNHI, Eth\_P\_Mort, Eth\_P) and Other Groups (Eth\_O\_CNHI, Eth\_O\_Mort, Eth\_O).

## **I.5.4 Meshblocks and Area Units**

Meshblocks and Area Units have already been described on page 42. Meshblocks are preferred over Area Units as they provide more discrimination in terms of record linkage.

A meshblock of residence was recorded for all census records, but was sometimes unable to be assigned to mortality records. Mortality records do, however, include at least one domicile code which was used as a 'second choice' measurement of location when the meshblock was missing. In order to allow linkage to take place in the absence of meshblock codes (or if the meshblock code was incorrect), all census records were also assigned their usual residence Area Unit code.

Census meshblock and Area Unit codes tend to change over time as populations expand or diminish and area boundaries are changed accordingly. The 2001 census used 2001 meshblock codes. Forward coding was required to change some mortality data into 2001 meshblock codes.

Three sources of address information were available for the mortality records – the NHI current file, the NHI archive file, and the Mortality Event file. Up to three meshblocks could therefore be assigned, whereby the meshblock codes were ranked according to how close the date of the address recorded was to the census. The closest date was ranked highest. Three meshblock variables were produced for matching, MB01\_1 -- MBO1\_3.

The NMDS file included dates and domicile codes for each hospital admission on record. Consequently, it was possible to order admissions and their associated domicile codes according to closeness to the census. Eighteen Area Unit Variables (AU\_1 to AU\_18) were created, with those recorded closest to census night given highest priority. In practice however only the four highest priority AUs were used in the linkage.

### **I.5.5 Country of Birth Variables**

Country of birth is recorded on both the mortality and NHI datasets. The mortality country of birth code was used for linkage (Bcountry). Where the country of birth was missing on the mortality events file, it was imputed from the most common value on the NHI files.

Country of birth information was grouped into the 9 categories: 1=Born NZ; 2=Born Australia; 3=Born British Isles; 4=Born Europe; 5=Born Pacific Islands; 6=Born Africa; 7=Born Americas; 8=Born Asia; 9=Born Elsewhere; 0=Missing.

Three other variables were also created that record other country of birth options from the NHI and mortality files (BthCountry1, BthCountry2, BthCountry3). These variables were used for clerical review. The variables were ordered according to the frequency of the value. For example, Bcountry1 = most common place of birth recorded, Bcountry2 = second most common place of birth recorded, and Bcountry3 = third most common place of birth recorded.

### **I.5.6 Interaction of country of birth and ethnicity variables**

Ideally all variables used for linkage should be independent. However, experience from linkage of the earlier cohorts had shown that this was not the case for country of birth and ethnicity variables. (Hill et al. 2002) In particular the agreement weights were too high for links where there was either: agreement on ethnicity as Pacific and agreement on country of birth as Pacific; or agreement on ethnicity as Asian and agreement on country of birth as Asian. This occurred because decedents of Pacific or Asian ancestry were highly likely to have Pacific or Asian country of birth (respectively).

To get around this problem two additional variables were created whereby the census and mortality values were reassigned so that they did not agree. On the mortality file if someone was born in the Pacific and of Pacific ethnicity they were given a value of 5, otherwise they were given a value of 9 for missing. On the census file if someone was born in the Pacific and of Pacific ethnicity they were given a value of 2, otherwise they were given a value of 9 for missing. Similarly, mortality Asian born in Asian were given a value of 8, otherwise a value of 9 for missing, and on the census file, Asians born in Asian were given a value of 4, otherwise a value of 9 for missing.

Consequently, those links with complete agreement on ethnicity and country of birth when both variables were either Pacific or Asian actually registered a disagreement for these particular composite variables (EthPacFix and EthAsianFix) in QualityStage™ (All other comparisons would have a missing value on either the census or mortality file, thereby scoring no weight).

## **I.6. Record linkage process and outputs**

This chapter presents the outcomes of the record linkage process under the following headings:

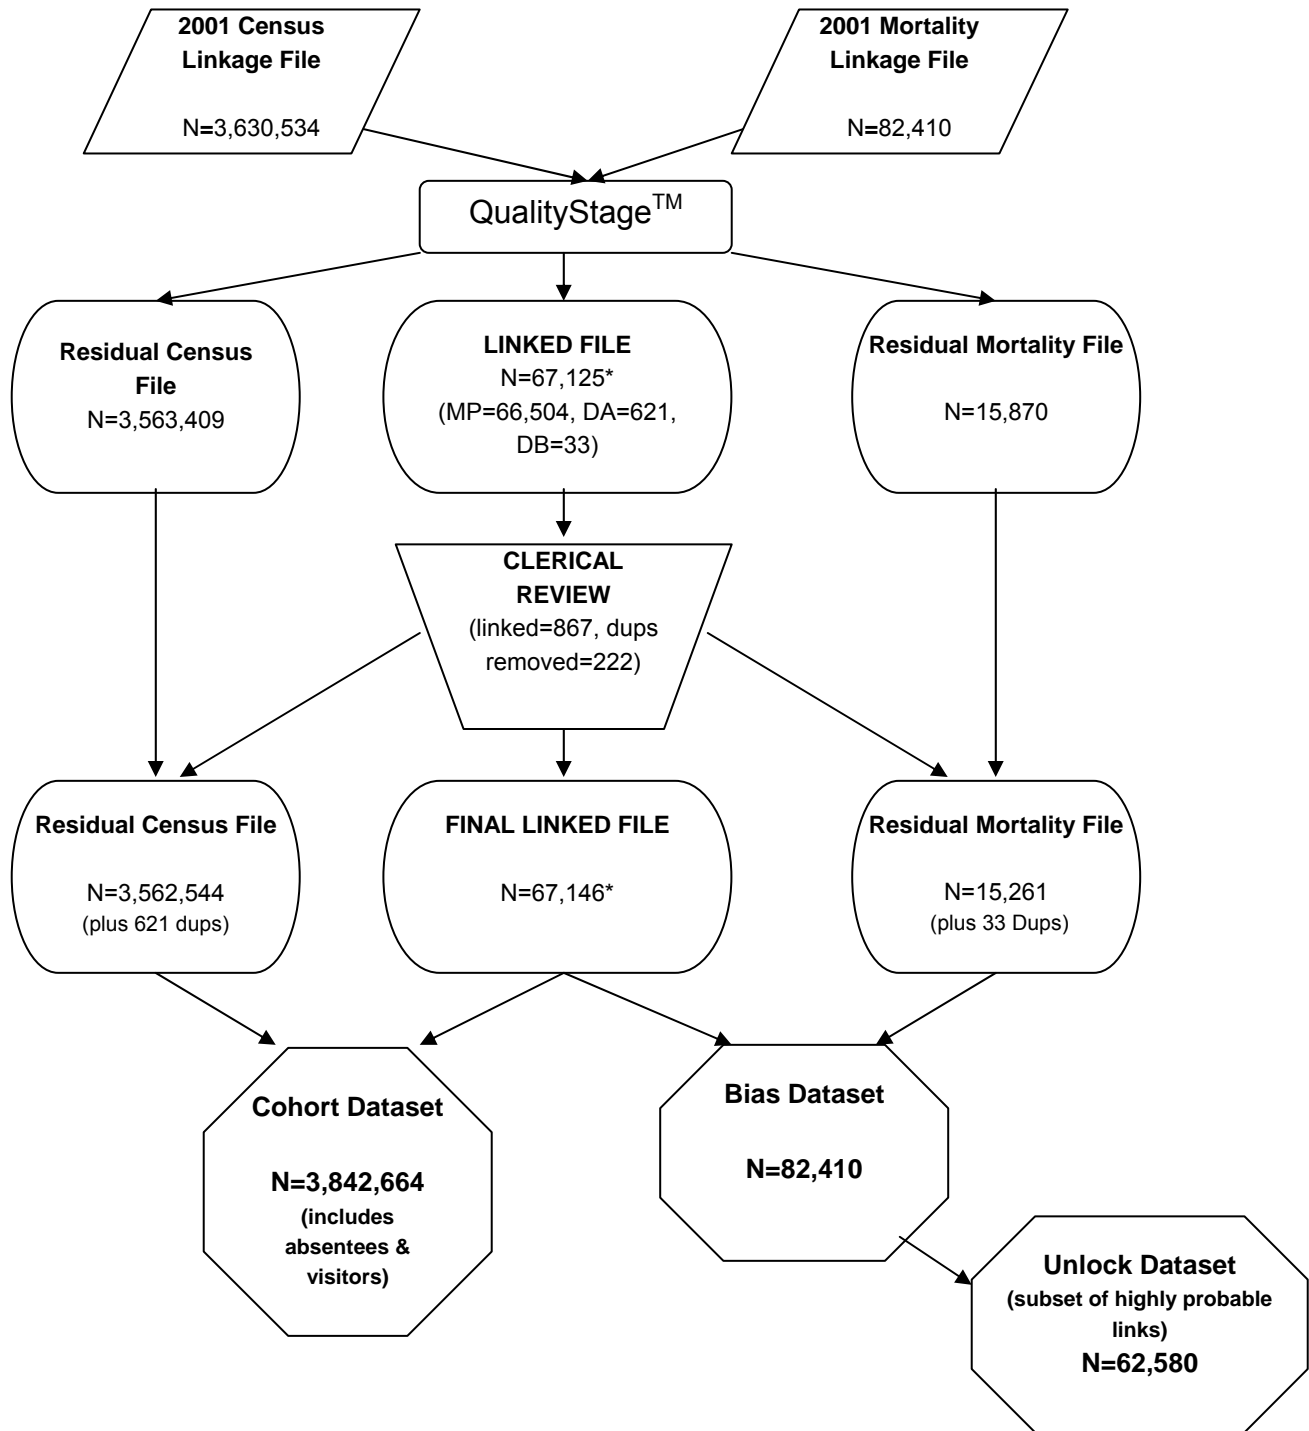

- 1) overview of the linkage process.
- 2) the final match-run strategy
- 3) the m and u probabilities and variable weightings from the first pass of the final match run
- 4) accuracy of the record linkage (false positives and positive predictive value)

This ordering is intended to provide a logical outline of the linkage process, rather than reflecting the exact chronological sequence of the work.

### **I.6.1 Overview of the linkage process**

The 2001 census included records for a total of 3,630,534 (RR) New Zealand residents on the 6th March 2001 (File A). For the three years following the census night, NZHIS received 82,410 (RR) mortality records for persons who died during this period. The flow of census and mortality records through the linkage process is shown in Figure 5.

**Figure 5: Flow diagram of census and mortality records for the 2001-04 cohort<sup>3</sup>**

<sup>3</sup> All these numbers have been random rounded to multiples of three according to Statistics New Zealand protocols

\* 67,146 (random rounded) arises from : [67,125 linked in passes] + [867 linked in clerical review] – [222 duplicates removed in clerical review] – [621DA pairs removed]

## **I.6.2 The final match run strategy**

Various match-run iterations were trialled to determine the 'best' linkage strategy. The final match run strategy (including the percentage of links) is presented in Table 4. Overall, 81.5% of mortality records were linked to a census record, equating to 67,146 linked pairs.

Clerical review was undertaken by running a program in SAS (MBCRprog.sas) written after we first looked at what were and were not satisfactory selection criteria for a sample of the data. QualityStage™ passes 8, 9 and 10 were run using blocking variables Meshblock 1, 2 and 3, using the same specifications as for passes 1, 2 and 3, but with the addition of a +/-1 day and +/-1 year tolerance. These passes 8, 9, and 10 all used the residual files from pass 7 with zero cutoff, and the possible links from all three passes were pooled as it was highly unlikely that any record would be linked on more than one of these passes. The SAS program investigated the possible links and using the criteria rules we had determined earlier and making use of the extra mortality dataset variables, decided which links would be accepted.

Details of the Clerical Review SAS program comparisons in order looked at :

1. Accept if link weights greater than or equal to 14.6.
2. Reject those with weights less than 7.9.
3. Reject those with complete missing or incorrect ethnicity who do not have correct sex and day, month or year of birth (day or year but not both can have a +/- 1 tolerance).
4. If sex and year correct but day and month missing then reject.
5. If sex correct but either (no day, month or year information), or only day or month, or (day or year correct but month incorrect) then reject.
6. If sex, month, year, any of the three country of birth variables, ethnicity, ethnicity/country fix all correct (i.e. ignoring day of birth), then if (year of birth  $\geq 1925$  and weight  $> 8.5$ ) or (year of birth  $< 1925$  and weight  $\geq 11$ ) then accept, otherwise reject.
7. If sex, day, month, any country of birth, ethnicity all correct then if (weight  $\geq 11$ ) or (agreed that born in NZ and weight  $\geq 8.5$ ) then accept, otherwise reject.
8. If sex incorrect but day, month, year, country of birth, and all ethnicities are correct, then if weight  $\geq 8.5$  then accept, otherwise reject.
9. If sex incorrect then reject.
10. If month of birth incorrect but day, year, country of birth, Maori, Pacific and Asian ethnicities are all correct, and country of birth is not NZ, then accept. If country of birth is NZ then reject.

11. If sex, month, year and all ethnicities correct, then if (country of birth is NZ or missing) and ((year of birth  $\geq$  1925 and weight  $>$  8.5) or (year of birth  $<$  1925 and weight  $\geq$  11)) then accept, otherwise reject.
12. If sex, month, year, any country of birth, Maori, Pacific and Asian ethnicities all correct and country of birth is not missing or NZ then accept.
13. If sex, month, year ( $\pm 1$ ), country of birth, Maori, Pacific, Asian all correct but nonMPA is incorrect, then if have Maori and/or Pacific and/or Asian ethnicities then accept, otherwise reject.
14. If sex, day, month, year ( $\pm 1$ ), all ethnicities all correct then if country of birth missing or NZ and weight  $\geq$  11 then accept, otherwise reject.
15. If all ethnicities not correct then reject.
16. Remaining combinations all rejected.

At the end of the linkage process there were three final output files: a final linked file, a final residual census file and a final residual mortality file (see Figure 6).

**Table 4: Final match-run strategy, 2001-04**

Pass and blocking variable(s)	Main match specifications	Matching variables	Links from each pass (includes duplicates)	% total mortality records linked
1. Meshblock 1	Match cut-off weight = 11.90	Sex, day of birth (array), month of birth (array), year of birth (array), Maori, Pacific, Asian, Other, birth country, Asianfix, Pacificfix	46,798 links from 82,408 records [includes 240 exact DA, 20 exact DB pairs]	(56.79%)
2. Meshblock 2	Match cut-off weight = 11.90	As for pass one	3382 links from 35,590 records [23 DA and 2 DB pairs]	(4.10%)
3. Meshblock 3	Match cut-off weight = 11.90	As for pass one	118 links from 32,206 records [no DA or DB pairs]	(0.14%)
4. Area Unit_1 and Sex	Match cut-off weight = 14.40	day of birth (array), month of birth (array), year of birth (array), Maori, Pacific, Asian, Other, birth country, Asianfix, Pacificfix	7493 links from 32,088 records [includes 194 exact DA and 7 exact DB pairs]	(9.09%)
5. Area Unit_2 and Sex	Match cut-off weight = 14.40	As for pass 4	6277 links from 24,588 records [126 DA dups and 5 DB pairs]	(7.62%)
6. Area Unit_3 and Sex	Match cut-off weight = 14.40	As for pass 4	2004 links from 18,306 records [32 DA]	(2.43%)
7. Area Unit_4 and Sex	Match cut-off weight = 14.40	As for pass 4	432 links from 16,302 records [5 DA]	(0.52%)
<b>CLERICAL REVIEW</b>	Conducted in SAS		866 additional links	(1.05%)
	Removal of 223 duplicates		223 duplicates removed	(-0.27%)
<b>TOTAL</b>			<b>67,147 links from</b>	<b>81.48%</b>

Pass and blocking variable(s)	Main match specifications	Matching variables	Links from each pass (includes duplicates)	% total mortality records linked
				<b>82,408 records</b>

### **I.6.3 The final m and u probabilities and variable weightings**

Table 5 lists the u and m probabilities for the pass 1 match run. Note that although the agreement and disagreement weights are similar for all passes, they do vary. Table 6 is indicative only of the agreement and disagreement weights for other passes.

**Table 5:  $u$  and  $m$  probabilities, and agreement and disagreement weights for matching variables for the pass 1\***

Matching variable	Value	$m$ probability	$u$ probability	Agreement weight	Disagreement weight
Sex	1 = Male	0.99	0.49	1.02	-5.67
	2 = Female	0.99	0.51	0.95	-5.60
Day of Birth	Range 1 to 31	0.97	Mainly 0.03	4.80 to 5.68	-5.03 to -5.00
Month of Birth	Range 1 to 12	0.98	0.08 to 0.09	3.45 to 3.67	-5.52 to -5.50
Year of birth (examples by decade)	1910	0.99	0.00	9.41	-6.64
	1920	0.99	0.01	7.61	-6.63
	1930	0.99	0.01	7.11	-6.63
	1940	0.99	0.01	6.72	-6.63
	1950	0.99	0.01	6.28	-6.62
	1960	0.99	0.02	5.97	-6.62
	1970	0.99	0.01	6.11	-6.62
	1980	0.99	0.01	6.21	-6.62
	1990	0.99	0.02	5.94	-6.62
	2000	0.99	0.01	6.12	-6.62
Country of Birth	1 = NZ	0.85	0.80	0.09	-0.44
	2 = Australia	0.85	0.02	5.78	-2.71
	3 = British Isles	0.85	0.06	3.74	-2.64
	4 = Europe	0.85	0.02	5.68	-2.71
	5 = Pacific Is	0.85	0.03	4.71	-2.68
	6 = Africa	0.85	0.01	6.36	-2.72
	7 = Americas	0.85	0.01	6.92	-2.72
	8 = Asia	0.85	0.04	4.24	-2.67
	9 = Other	0.85	0.00	8.25	-2.73
Maori	1 = Maori	0.80	0.14	2.48	-2.09
	0 = non-Maori	0.85	0.85	0.01	0.00
Pacific	2 = Pacific	0.80	0.06	3.67	-2.22
	0 = non-Pacific	0.93	0.93	0.01	0.00
Asian	4 = Asian	0.80	0.06	3.64	-2.22
	0 = non-Asian	0.92	0.92	0.01	0.00
Other Ethnicities	5 = Other	0.80	0.80	0.01	-0.01
	0 = non-Other	0.80	0.19	2.07	-2.01
<u>Fix for Asian</u>	4 = Asian born in		0.04	..	-3.58

Matching variable	Value	<i>m</i> probability	<i>u</i> probability	Agreement weight	Disagreement weight
ethnicity and country of birth combination <sup>†</sup>	Asia on Census 8 = Asian born in Asia on Mortality		0.00		-3.64
Fix for Pacific ethnicity and country of birth combination <sup>†</sup>	2 = Pacific born in Pacific Islands on Census 5 = Pacific born in Pacific Islands on Mortality		0.03 0.00	.. 	-3.60 -3.64

\* pass 1 was the first run with meshblock 1 and obtained the most links. Other passes have very similar probabilities and weights to pass 1.

<sup>†</sup> as these variables were set up to always disagree, or be missing, only the disagreement weights are presented. The disagreement weight used by QualityStage™ is the highest (closest to 0) of the disagreement weights for the different values.

#### I.6.4 Accuracy of the record linkage (false positives and positive predictive value)

Positive predictive values were estimated using the duplicate method. The PPV for passes 1 to 6 is shown in Table 6. The overall PPV for linkage of the 2001 cohort was estimated as over 97%. It is difficult to estimate a more precise overall PPV because of the small numbers linked in some passes and the very selective picking of acceptable matches in the Clerical Review stage.

**Table 6: Positive predictive value (PPV) and expected number of false positives (E[FP]) for passes 1 to 6 of the final match-run, 2001-04**

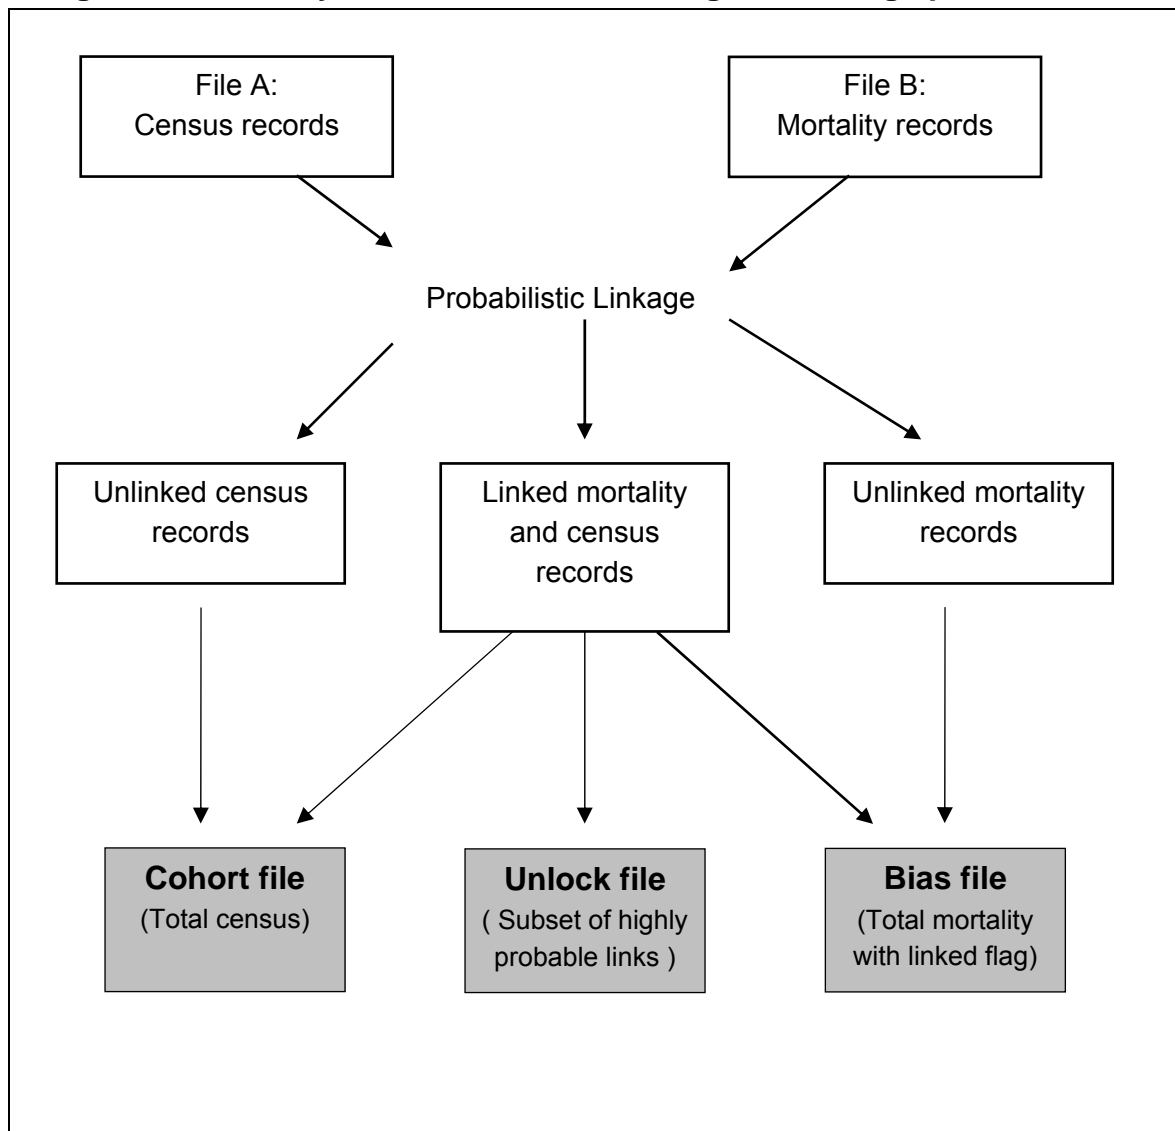

Pass	Blocking Variable	Link pairs	Duplicate method E[FP]	PPV
1	Meshblock 1	46,798	185	99.6%
2	Meshblock 2	3,382	229	93.2%
3	Meshblock 3	118	0	..

## I.7. Cohort, bias and unlock files

The linkage process produced three files that were released for use in the data lab at SNZ: the cohort, bias and unlock datasets.

Variables included in the three NZCMS 2001-04 datasets can be found in the Appendix.

**Figure 6: Summary of flow of records through the linkage process**

# **Part II Weighting of 2001-04 Cohort to Adjust for Linkage Bias**

## **II.1. Introduction**

The NZCMS used anonymous and probabilistic record linkage of census records with mortality records to create the 2001-04 cohort. The methods for linking the census and mortality records are described in Part I of this report. The record linkage process was successful in linking 81.5% of eligible mortality records to a census record.

If the probability of linkage varies by factors of interest (e.g. age, ethnicity, socio-economic position) then the linkage will result in biased estimates of association between those factors and mortality. Incomplete linkage between census and mortality files means that the vital status of some members of the census cohort are misclassified as alive three years after the census when in reality they have died. In previous cohorts, when the mortality and census records were stratified by demographic characteristics (age, sex and ethnicity), geographical distribution (rural/urban and Regional Health Authority), socioeconomic measures (NZ Deprivation Index), time following census and the level of mobility in the area unit, the proportion of mortality records linked varied by strata (i.e. linkage bias).

In order to compensate for linkage bias the records were weighted. The weighting will adjust for misclassification of the mortality outcome in the future cohort analyses. The method used to calculate the weighting factors is described in the following sections.

## **II.2. Description of Bias Dataset**

A detailed description of the variables on the bias dataset is given in Table 54, in the appendices. In summary, the variables include sex, age at census and age at death, ethnicity, rurality of place of residence, Deprivation Index (NZDep01), Social Fragmentation Index, level of mobility in area unit, Cause of Death, and a flag indicating whether or not the record was linked to a census record. The Ethnicity variable is a derived variable, whereby ethnicity has been grouped according to the Prioritised, Sole, and Total ethnic groupings, with four categories – Māori, Pacific, Asian and NonMPA (other).

The social fragmentation index was developed in 2005 as a measure of the degree of social fragmentation at the level of the neighbourhood (which in this case is the census area unit). It was included with the bias dataset because of the possibility that residential mobility reduces the likelihood of the linkage of a mortality record to a census record. “Level of mobility” groups area units according to the proportion of respondents in the area unit who did not live in the same area unit at the time of the previous census. As the linking process can only link records within a meshlock or area unit, a high level of residential mobility is likely to be associated with low levels of linkage.

### **II.3. Linkage by social and demographic variables**

The overall percentage of deaths linked for the 2001-04 cohort was 81.5%. The total number of deaths and proportion of mortality records linked by Sex, Age, Ethnicity, NZ Deprivation Index, Social Fragmentation Index, Rurality, Regional Health Authority, Broad Cause of Death Categories and time lapsed after census are shown in Table 7.

Linkage was lowest for:

1. Ages 25-34 years
2. External causes of death (unintentional and intentional injury, including suicide)
3. People living in rural areas
4. People living in areas of high residential mobility
5. People living in the Northern RHA (North of Bombay hills)
6. People living in high deprivation areas
7. People living in areas with a high social fragmentation score
8. Pacific and Asian people, (Maori were intermediate and nMPA had the highest rates of linkage)

Much of the difference in linkage rates by geographical variables and New Zealand Deprivation Index was due to differences in population distribution by age, sex and ethnicity. This finding is consistent with results reported for the earlier cohorts.(Blakely et al. 1999; Fawcett et al. 2002; Hill et al. 2002) Rurality, level of mobility, and cause of death were also important independent risk factor for linkage.

Furthermore, there was a significant interaction in linkage rates for age and sex groups. Linkage was higher for females compared to males for people aged less than 65 years, similar between sexes for ages 65-74 years, and linkage rates were less for females than males for ages 75 years and older.

Time since the census did not affect the likelihood of a mortality record being linked, once other factors were taken into account.

To determine which variables should be used to stratify the dataset for the creation of weights, the independent association of each variable with the probability of linkage using multivariate regression was looked at. A number of models were investigated. Table 8 shows the relative risk of linkage for the final model with all other variables entered as covariates and with an interaction for sex and age, allowing for by cross-classifying sex and age, and setting males aged greater than or equal to 85 years as the reference category. Other interactions were also investigated however no others were retained.

Of note, the level of mobility of the decedent's area unit was a strong prediction of linkage success. This is a variable we did not explicitly test in previous cohorts, although it is likely that without "level of mobility" other correlated variables such as age, ethnicity, and NZDep would have strong associations.

## **II.4. Methods for calculation of weights to adjust for linkage bias**

### **II.4.1 Summary**

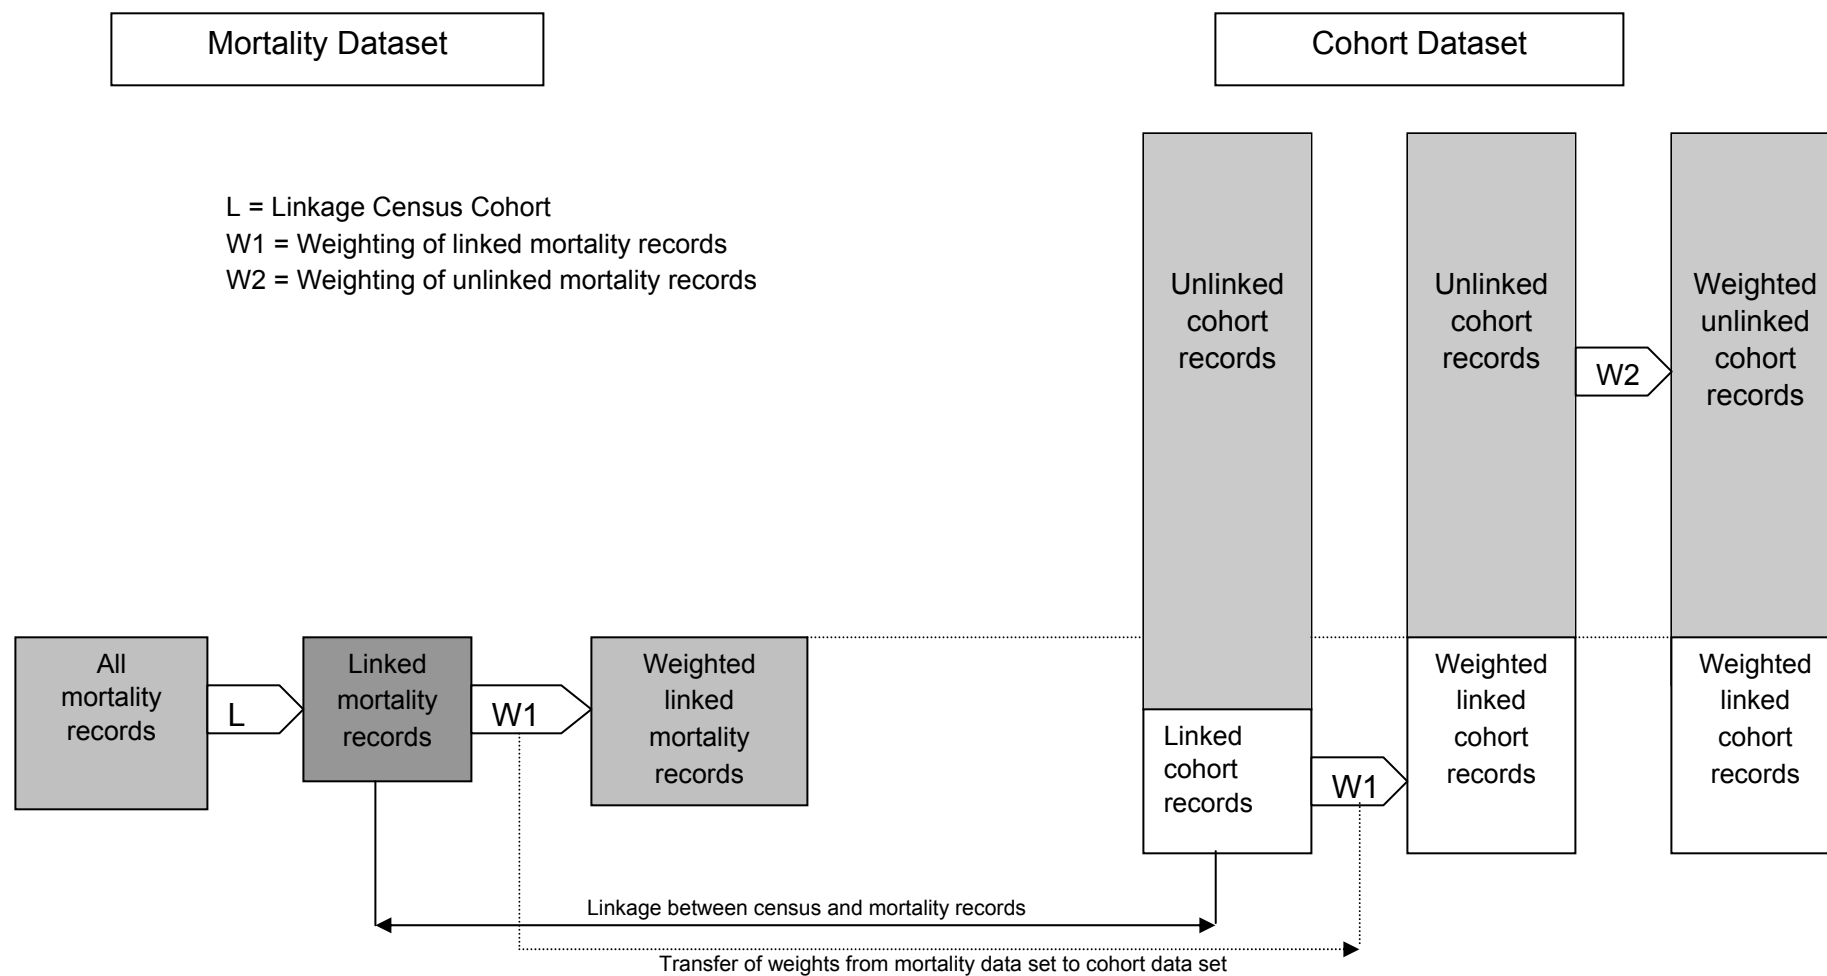

The method for weighting the cohort was essentially similar to that used for previous NZCMS cohorts.(Fawcett et al. 2002) A two-step process was used to create the weights to adjust for linkage bias. The linked mortality records were weighted in order to represent the full mortality records.

This entailed two weighting processes.

1. Based on a dataset of all mortality records, weights were created that were the inverse of the probability of linkage within socio-demographic strata.
2. The unlinked records were weighted to adjust for the non-linkage of some mortality records.

This process is summarised in Figure 7.

**Figure 7: Diagrammatic summary of the linkage weighting process**

## II.4.2 Stratification of the data by demographic variables

To correctly weight each linked record on the census-mortality data-sets, weights needed to be applied that varied by demographic strata. The strata that we used for the initial weighting were:

- Sex (male, female)
- Age group (7 groups according to age at census night; 0-14, 15-34, 35-49, 50-64, 65-74, 75-84 and 85+ years)
- Ethnic group (4 groups based on the prioritised classification).
- Level of Mobility (4 groups)
- Cause of death (6 groups)
- Rurality (rural, urban).
- RHA (4 groups)

These variables were chosen because in the multivariate regression they contributed most to the reduction in deviance. The Deprivation and Social Fragmentation indexes were not included as the reduction in deviance was much less for these variables than for others included in the model.

Potentially this stratification regime could result in 10,752 separate strata. However, to avoid weights of zero (no deaths in strata), or undefined weights (no linked mortality records in strata), strata were amalgamated to obtain a minimum strata size. The decision to combine strata was based on the number of deaths and proportion linked in each stratum.

Age and Ethnic groups were never combined, and Sex groups were combined only when absolutely necessary to ensure cells of adequate size.

The success of the initial weighting was investigated by comparing the weighted number of linked deaths and the known number of actual deaths, by strata age groups (broad groupings and five year age groupings), sex, ethnicity, RHA, rurality, cause of death and Territorial Authority. The weighted numbers were found to be very accurate for the broad groupings of variables but less so for the detailed groupings. The main exception to this was for ages less than 35 years. The problems with the weightings in this age group arose because the pattern of linkage was very variable even within five-year age groupings for less than 35 years. To improve the function of the weights the stratification strategy was changed. The deaths were stratified by 5-year age group, sex and ethnicity, and then where numbers allowed, by cause of death, and urban/rural place of residence.

In order to produce weights that ensured weighted numbers of linked deaths were the same as the known number of actual deaths, a secondary adjustment to the original weightings was done. This adjustment ensured that the weights accurately predicted the total number of deaths for strata of age (5 year groups), sex, and ethnicity (prioritised definition). The unadjusted weight is 'W\_ Base' and the adjusted weight is 'W\_AgEthAdj'. The weighted

and raw counts of death for various strata are given in Table 9. Weighted numbers of linked deaths were within one percent of actual numbers of deaths in most strata, also shown in Table 9.

**Table 9: Weighted numbers of linked deaths and actual deaths on Bias data-set, 2001-04**

### II.4.3 Weighting of non-linked census records

Linked cohort members represent a person who was alive at the time of the 2001 census but died in the subsequent three years. Applying weights to the linked cohort members compensates for the incomplete linkage of the mortality data-set to the census, and allows the calculation of mortality rates for the total population. It is however also necessary to weight down the unlinked cohort members to allow for the fact that some of the unlinked census records actually did die during follow-up.

The weighting thus far has addressed only the linked census-mortality records, which account for approximately one percent of the total number of census records in each cohort. In order for the weighted sum of *all* census records in each cohort to still equal the total number of census records, each *unlinked* census record must also be assigned a weight of (usually) just less than 1.0. The unlinked mortality records represent a census record for which the mortality outcome is misclassified as not dead. The true number of cohort members not dead at the end of the follow-up period can be estimated by subtracting the number of weighted number of deaths on the census data from the total number of census cohort records. See Technical Report 5 for a more detailed description of the method- (Fawcett et al. 2002).

As with the linked records two weights were calculated (W\_Base and W\_AgEthAdj). Any other linkage weights produced in the future for specific analyses will also require separate weighting of the unlinked cohort records.

## **II.5. Limitations of the weighting and conclusions**

The weightings described here produce relatively stable adjustments for linkage bias. However, the performance of the weights at a sub-national level has not been investigated. Table 55 in the appendices give counts of linked actual and weighted deaths by territorial authority, regional council, and district health board. The performance of the weights to adjust for linkage bias will therefore need to be checked and an area based scaling of the Base weight may be required for these analyses.

The use of linkage weights should enable adjustment for linkage bias and the calculation of stratum specific mortality rates for a full range of socio-economic variables.

It is also noted that in the weighting of 2001-04 records, we used the “level of mobility” variable. Having done so, NZDep no longer contributed to explaining linkage success, and was not included as a weighting variable. This creates a discontinuity of methods between the earlier and 2001-04 cohorts, but also an adherence to “best performance” in the 2001-04 cohort. We decided the latter principle mattered most.

## **Part III Calculation of ‘Unlock Ratios’**

### **Introduction**

This Section describes the calculation of ratios to adjust for the undercounting of Māori , Pacific and Asian deaths in the New Zealand Death records for the 2001-04 NZCMS cohort.

The analyses in this technical report are based on the analysis of the 2001-04 Unlock Dataset. The unlock dataset is a subset of mortality records that were successfully linked back to the 2001 census data for which there is a high probability that the links were in fact true links. The production of the unlock dataset is described in Part I of this technical report. (see page 53).

### **III.1. Variables included in the unlock file**

Table 58, in the appendices, gives details of the variables in the 2001-04 Unlock Dataset.

This section of the technical report

1. Describes the method used to calculate the adjustment ratios
2. Provides a list of tables of adjustment ratios for the 2001-04 census-mortality cohort.
3. Discusses the possibility of misclassification bias and residual systemic bias in the analyses

For a more detailed justification of the methods and advice and guidance on the use of the results in this report please refer to the earlier technical report for the first four cohorts. (Ajwani et al. 2002)

## **III.2. Summary of Methods to Calculate Adjustment Ratios**

### **III.2.1 Weighting of Unlock DataSet to represent all mortality records**

The first step in the calculation of mortality data was to weight the subset of highly probable links to represent the full mortality dataset. A flag on the dataset including all mortality records indicated whether the record was also on the unlock data set (that is the subset of highly probable links).

Just as weights were created to weight the linked records to represent the total mortality dataset, weights were created to weight up the highly probable links to represent the total mortality dataset. The weighting was done within strata of:

- Sex (male, female)
- Age group (7 groups according to age at census night; 0-14, 15-29, 30-44, 45-64, 65-74, 75-84 and 85+ years)
- Ethnic group (4 groups based on the prioritised classification; Māori, Pacific, Asian, nonMPA).
- Level of Mobility in the area unit (4 groups; <45%, 45-54%, 55-69%, >=70% of residents in the area unit who did not live in the same area unit at the time of the last census)
- Cause of death (6 or 8 groups Cancer; CVD excl IHD; IHD; Respiratory; Congenital, Perinatal, SIDS; Unintentional injury; Suicide; Violent; Other Causes)
- Rurality (rural, urban).

The weight (W\_unlock) was then transferred to the subset of highly probable links.

### **III.2.2 Calculation of Ratios to adjust for Numerator-Denominator Bias**

The numerator-denominator bias was determined by cross classifying census ethnicity by the death registration form ethnicity or NHI Ethnicity. Further cross-classification was conducted by strata of sex, age at death, small area deprivation, RHA, rurality, and cause of death, in order to determine the heterogeneity of any numerator-denominator bias. The adjustment ratios were calculated based on total, prioritised and sole classifications for four ethnic

groups – Māori, Pacific, Asian, and NonMPA. Note that the Prioritised Maori ethnic group is the same as the Total Maori ethnic group. When comparisons were made between census and mortality files, the same classification scheme was used on both files (i.e total, prioritised or sole). For example, we do not report 'sole mortality counts compared to total census counts'.

### III.3. Unlock Ratios for Mortality Data

#### III.3.1 Full Population

Table 10 shows the number of deaths in 2001-04 according to the total ethnicity definition, for both the 2001 census ethnicity data and the 2001-04 mortality data. The data are largely concordant. For example, of the 82,404 eligible mortality records, our weighted estimation using the HPL data-set estimates that 7,419 of these deaths were Māori on the census form (using total concept) and 7,539 were Māori on the NMDS mortality data. That is, mortality data actually slightly overestimates the number of total Māori deaths (using the 2001 census as the gold standard), with a census-mortality ratio of 0.98. The estimated difference in counts for non-Māori between census and mortality data is necessarily the same as the difference for Māori, ie 120 or 117 (due to random rounding of all SNZ data to a near multiple of three, number will not always appear to be exactly same in tabular output). However, because there are so many more non-Māori deaths, the census to mortality ratio rounded to two decimal places is actually 1.00.

For the total Pacific counts, mortality data also appears to overestimate the ‘true’ census count by about 2% (ie, ratio of 0.98), but there appears to be a 2% underestimate of the total Asian deaths on mortality data (ie, ratio of 1.02). Due to likely imprecision in our linkage and weighting schema, it is probably safest to conclude that there is very little difference – if any – between census and mortality data in 2001-04 for Māori, Pacific and Asian ‘total’ definitions.

**Table 10: Census Total ethnicity by death registration form Total ethnicity, 2001-04 NZCMS cohort**

Ethnicity	By Variable	Census Ethnicity	Census Deaths	Mortality Deaths	Census to Mortality Ratio
Total Ethnicity All Data	Maori		7,419	7,539	0.98
	Non-Maori		74,985	74,868	1.00
	Pacific		2,448	2,493	0.98
	Non-Pacific		79,956	79,914	1.00
	Asian		1,236	1,215	1.02
	Non-Asian		81,171	81,189	1.00
	NonMPA		73,089	72,051	1.01
	Maori/Pacific/Asian		9,315	10,356	0.90

The last panel in Table 10 gives the results for a total nonMPA group – that is anyone who was identified as an ethnic group other than Māori, Pacific or Asian. (This is not a commonly used group.) Due to large numbers, the

census to mortality ratio is close to 1.0 (ie, 1.01). But for the complementary group of people who reported only ethnicities within the three Māori, Pacific and Asian categories, there were notably less on the census data (ie, ratio of 0.90). This arises because more people tend to self-identify as two or more ethnic groups on 2001 census data compared to that elicited on mortality data.

Table 11 shows the data cross-classified by prioritised ethnicity. As the ethnic groups are now mutually exclusive, it is possible to present the table in a cross-classified manner – hence the variation in layout from the previous table for total ethnicity results. Overall there was no substantial difference between the census and mortality counts. That is all ratios are close to 1.0.

**Table 11: Census prioritised ethnicity by death registration form prioritization ethnicity, 2001-04 NZCMS cohort**

		Death registration form Prioritised Ethnicity					Census to Mortality Ratio
		Maori	Pacific	Asian	NonMPA	Total	
By Variable	Census Prioritised Ethnicity	Deaths	Deaths	Deaths	Deaths	Deaths	
All Data	Maori	6,621	21	6	774	7,419	0.98
	Pacific	36	2,250	6	81	2,373	0.97
	Asian	6	42	1,059	69	1,170	1.01
	NonMPA	879	126	87	70,353	71,442	1.00
	<i>Total</i>	<i>7,539</i>	<i>2,439</i>	<i>1,155</i>	<i>71,274</i>	<i>.</i>	<i>.</i>

When 'sole' ethnic categorisation is used (Table 12), the mortality data overcounts the number of Maori deaths relative to the census by about 16% (ie,  $[1.0 / 0.86] - 1 = 0.16$ ). There is also a small (3%) over count of Pacific deaths. In practice, this means that if the 'sole' categorisation of ethnicity is used to calculate mortality rates using unlinked data, the numerator-denominator bias will bias the Māori and Pacific rates upwards. The reason that there is more bias with the sole compared to total or prioritised definitions is that fewer 2001-04 deaths than expected have two or more ethnicities on their death registration form, resulting in high sole ethnicity counts (relative to the 2001 census).

**Table 12: Census sole ethnicity by death registration form sole ethnicity, 2001-04 NZCMS cohort**

		Death registration form Sole Ethnicity					Census to Mortality Ratio
		Maori	Pacific	Asian	Remainder	Total

	Pacific	18	2,067	6	105	2,196	0.97
	Asian	.	15	996	90	1,098	1.01

		Death registration form					
		Sole Ethnicity					
		Maori	Pacific	Asian	Remainder	Total	
By Variable	Census Sole	Deaths	Deaths	Deaths	Deaths	Deaths	Census to
	Ethnicity						Mortality Ratio
	Remainder	1,392	183	87	71,520	73,179	1.01
	<i>Total</i>	<i>6,891</i>	<i>2,274</i>	<i>1,086</i>	<i>72,153</i>	<i>.</i>	<i>.</i>

The remaining sections in this Chapter present the same tables as above, but separately by strata of sex, age, small area deprivation, RHA, rurality, and cause of death.

### III.3.2 By Sex

There was no notable difference in unlock ratios by sex, with the possible exception of Pacific sole results (Table 13).

**Table 13: Census by death registration form stratified by sex, 2001-04 NZCMS cohort. TOTAL ethnicity**

Ethnicity	Sex	Census Ethnicity	Census Deaths	Mortality Deaths	Census to Mortality Ratio
Total Ethnicity	Males	Maori	4,095	4,140	0.99

### III.3.5 By RHA

Difference by RHA for 2001-04 are not as notable as those previously found in the 1980s and early 1990s. However, it is interesting to see that the total and prioritised Māori ratios are higher in the Southern RHA, but the sole Māori ratio is lowest in the Southern RHA. This suggests that the under recording of multiple ethnicities on mortality data (relative to census data) is most prominent in the South of New Zealand.

**Table 22: Stratification by Regional Health Authority, 2001-04 NZCMS cohort. TOTAL ethnicity**

Ethnicity	By Variable	Census Ethnicity	Census Deaths	Mortality Deaths	Census to Mortality Ratio

## III.4. Unlock Ratios for NHI Data

There is a practice by some researchers and health analysts to use the ethnicity field from the NHI file. Hence, we also provide the following unlock ratios from the census compared to the NHI file.

### III.4.1 Total Population

In contrast to the mortality data, the NHI ethnicity data tends to underestimate census total and prioritised counts for Māori, Pacific and Asian, ie, census to mortality ratios ranging from 1.10 to 1.21.

**Table 31: Census total ethnicity by NHI registration form total ethnicity, 2001-04 NZCMS cohort**

Ethnicity	By Variable	Census Ethnicity	Census Deaths	NHI Deaths	Census to NHI Ratio
Total Ethnicity All Data	Maori		7,422	6,546	1.13
	Non-Maori		74,985	75,861	0.99
	Pacific		2,451	2,190	1.12
	Non-Pacific		79,953	80,217	1.00
	Asian		1,233	1,026	1.21
	Non-Asian		81,171	81,381	1.00
	NonMPA		73,089	73,149	1.00
	Maori/Pacific/Asian		9,315	9,255	1.01

**Table 32: Census prioritised ethnicity by NHI registration form ethnicity, 2001-04 NZCMS cohort**

		NHI Prioritised Ethnicity					
		Maori	Pacific	Asian	NonMPA	Total

### **III.5. Conclusions**

There was little difference in recoding ethnicity (Total and Prioritised definitions) between census and mortality data during 2001-04. This is good news. It also suggests that the collection of ethnicity data on health data in a manner as close to that on census data works for getting accurate health statistics.

## **Part IV Appendices**

## **IV.1. Variables included in the cohort file**

Those variables included in the cohort file are presented in the following table.

Table 52 lists the name of each variable, variable format and the variable label, and brief explanatory notes where applicable.

For a few variables an extended explanation is provided, where required, in the pages following the table.

A detailed list of variable formats (as used in SAS) is included in the Table 53. These provide labels for the possible values of each variable.

**Table 52: Description of main Variables in the Cohort datasets 1981, 1986, 1991, 1996 and 2001**

<b>VAR: AnyAV</b>	<b>Avoidable Mortality Flag (First Version)</b>	<b>1981,1986,1991,1996</b>
<b>VAR: AnyAv</b>	<b>Avoidable Mortality Flag</b>	<b>2001</b>
<b>Note: Interim Avoidable mortality flag 26/8/2003 for 81,86,91 &amp; 96</b>		
<b>This is the version of the variable in the datalab using informat iavmrt.</b>		
<b>New version for 2001 used informat i10avmrt. (now i10av.)</b>		
<b>2001 version includes intermediary codes for deciding Amenable variable</b>		
<b>2001 version final variable just has values 0, 1 and 3.</b>		
<b>Code 3 technically non-avoidable but we will investigate further in datalab</b>		

### Format: fAnyAv

0='Non-Avoidable Mortality'	1='Avoidable Mortality'
3='Avoidable Mortality >= 75'	5='Amenable'
6='50% of deaths randomly assigned as amenable'	12='<45'
13='=<45'	14='Females';

### Note: Final Avoidable Mortality Flag 9/12/2003

This is the version we should have had if it had been ready in time.  
We can manipulate the other variable to almost get these groupings

### inFormat: inavmrt
